## To learn more about ON Semiconductor, please visit our website at www.onsemi.com

Please note: As part of the Fairchild Semiconductor integration, some of the Fairchild orderable part numbers will need to change in order to meet ON Semiconductor's system requirements. Since the ON Semiconductor product management systems do not have the ability to manage part nomenclature that utilizes an underscore ( $\_$), the underscore ( $\_$) in the Fairchild part numbers will be changed to a dash (-). This document may contain device numbers with an underscore (_). Please check the ON Semiconductor website to verify the updated device numbers. The most current and up-to-date ordering information can be found at www.onsemi.com. Please email any questions regarding the system integration to Fairchild questions@onsemi.com.

## FAN8060

### 1.2 MHz, 1 A Synchronous Step-Down DCIDC Regulator

## Features

- Current Mode Control
- Over 96\% Efficient
- Selectable Continuous Output Current: $500 \mathrm{~mA} / 1 \mathrm{~A}$
- 2.5 V to 5.5 V Input Voltage Range
- Output Voltage as Low as 1.2 V
- 1.2 MHz Operating Frequency
- Less than $1 \mu \mathrm{~A}$ Shutdown Current
- External Synchronization from 500 kHz to 2 MHz
- 100\% Duty Cycle
- Synchronous Switching FET; no Schottky Diode Required
- Stable with Ceramic Capacitors
- Light Load Mode with Pulse Skipping
- External Compensation
- External Soft-Start
- Overload / Short-Circuit Protection
- Under-Voltage Lockout
- Thermal Shutdown
- 10-Lead $3 \times 3 \mathrm{~mm}$ Green MLP Package

## Applications

- PDAs
- GPS Devices
- MP3 Players
- Mini PCI
- Digital Cameras
- Peripheral Ports
- DSP Core
- USB Devices
- PCMCIA
- Cable Modem
- Data Cards

## Description

The FAN8060 is a highly efficient, monolithic, currentmode, step-down synchronous regulator. It can provide 1 A continuous current from 2.5 V to 5.5 V input voltage. The output voltage can be adjusted from 1.2 V up to the input voltage with an external voltage divider.

External compensation and soft-start allow for design optimization and flexibility. High-frequency operation allows for all-ceramic solutions and small footprints. In addition, a user-selectable current limit provides protection against output overload and short circuit.

FAN8060 features pulse skipping to achieve higher efficiency during light load operation. $100 \%$ duty cycle capability enables power solutions to extend the drop out voltage.
Provision for external synchronization allows users to minimize input capacitors and manage EMI in solutions.

FAN8060 is available in a green, low profile, 10-Lead $3 \times 3 \mathrm{~mm}$ MLP package.

Figure 1. Typical Application Circuit

## Ordering Information

| Part Number | Operating <br> Temperature Range | Package | Packing Method |
| :---: | :---: | :--- | :---: |
| FAN8060EMPX | -40 to $+85^{\circ} \mathrm{C}$ | $10-$ Pin, $3 \times 3 \mathrm{~mm}$ Molded Leadless <br> Package (MLP) | Tape \& Reel |

## Pin Configuration

Figure 2. Pin Configuration (Top View)

## Note:

1. Connect exposed PAD to AGND

## Pin Definitions

| Pin | Name | Function |
| :---: | :---: | :--- |
| 1 | EN | Enable. Enables operation when pulled to logic HIGH. |
| 2 | AVIN | Analog Input Voltage. All internal control circuits are connected to this supply. |
| 3 | PVIN | Power Input Voltage. Power stage supply voltage. |
| 4 | SW | Switching Node. The drains of both PMOS and NMOS. |
| 5 | PGND | Power Ground. Power return and source of the power NMOS |
| 6 | SYNC | Synchronization. Use this pin to synchronize the part to an external clock. This pin also <br> controls current limit threshold. Tie to ground for 1.0 A or tie to VIN for 0.5 A continuous load <br> current. When an external clock is applied, the default current setting is 1 A. This pin has a <br> pull-down resistor of 450 K $\Omega$. |
| 7 | SS | Soft-Start. A capacitor connected between this pin and AGND can set soft-start time. |
| 8 | COMP | Compensation. Error amplifier output. Connect the external compensation network between <br> this pin and AGND. |
| 9 | FB | Output Voltage Feedback. Connect through a resistor divider to set the output voltage. |
| 10 | AGND | Analog Ground. Ground return for all internal control circuits. |

## Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only. All voltage values, except differential voltages, are given with respect to the network ground terminal. Stress beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device.

| Symbols | Parameter |  | Min. | Max. | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\text {PVIN }}$ | PVIN (AGND=PGND) |  | -0.3 | 6.0 | V |
| $\mathrm{V}_{\text {AVII }}$ | AVIN (AGND=PGND) |  | -0.3 | 6.0 | V |
| $\mathrm{V}_{\text {SW }}$ | Switch Voltage, SW to GND |  | -0.3 | $\mathrm{V}_{\text {IN }}+0.3$ or 6.0 | V |
|  | All other pins except COMP |  | -0.3 | 6.0 | V |
| TSTG | Storage Temperature |  | -65 | +150 | ${ }^{\circ} \mathrm{C}$ |
| TJ | Junction Temperature |  | -40 | +125 | ${ }^{\circ} \mathrm{C}$ |
| ESD | Electrostatic Discharge Protection | Human Body Model, JESD22-A114 | 2.0 |  | kV |
|  |  | Charged Device Model, JESD22-C101 | 2.5 |  |  |

## Note:

2. COMP pin has an internal clamp to 1.5 V .

## Recommended Operating Conditions

The Recommended Operating Conditions table defines the conditions for actual device operation. Recommended operating conditions are specified to ensure optimal performance to the datasheet specifications. Fairchild does not recommend exceeding them or designing to Absolute Maximum Ratings.

| Symbol | Parameter | Min. | Max. | Unit |
| :---: | :--- | :---: | :---: | :---: |
| $\mathrm{V}_{\mathbb{I}}$ | Supply Voltage | 2.5 | 5.5 | V |
| $\mathrm{~T}_{\mathrm{A}}$ | Ambient Operating Temperature | -40 | +85 | ${ }^{\circ} \mathrm{C}$ |

## Thermal Information

| Symbol | Parameter | Min. | Typ. | Max. | Units |
| :---: | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{T}_{\mathrm{STG}}$ | Storage Temperature | -65 |  | +150 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\mathrm{L}}$ | Lead Soldering Temperature, 30 Seconds |  |  | +300 | ${ }^{\circ} \mathrm{C}$ |
| $\theta_{\mathrm{JA}}$ | Thermal Resistance: Junction-to-Ambient |  | 49 |  | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $\theta_{\mathrm{JC}}$ | Thermal Resistance: Junction-to-Case ${ }^{(3)}$ |  | 8 |  | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $\mathrm{P}_{\mathrm{D}}$ | Total Power Dissipation in the package, $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}^{(3)}$ |  |  | 1.3 | W |

## Note:

3. Typical thermal resistance when mounted on a four-layer PCB. Actual results are dependent upon mounting method and surface related to the design.

## Electrical Characteristics

Functional Block Diagram

Figure 3. Functional Block Diagram

## Operation Description

The FAN8060 is a step-down converter operating in current-mode PWM architecture with a typical switching frequency of 1.2 MHz . At the beginning of each clock cycle, the P-channel transistor is turned on. The current in the inductor ramps up and is sensed via an internal circuit. The P-channel switch is turned off when the sensed current causes the PWM comparator to trip, which is when the output voltage is in regulation or when the inductor current reaches the current limit (set internally to 1.2 A, typically). After a minimum dead time to prevent shoot-through current, the N -channel transistor is turned on and the current ramps down. As the clock cycle is completed, the N -channel switch is turned off and the next clock cycle starts.

## Light Load Operation

As the output load reduces, the current in the inductor during off time is sensed across the low side MOSFET. When the current reverses direction, the low-side MOSFET is turned off and the high-side MOSFET is not turned on until the output is out of regulation.

## 100\% Duty Cycle Operation

As the input voltage approaches the output voltage, the controller starts to increase the duty cycle to maintain output regulation until duty cycle reaches $85 \%$. The controller then transitions to a $100 \%$ duty cycle mode over several cycles to support the load. When the dropout condition is met, the converter turns the P channel high side continuously on. In this mode, the output voltage is equal to the input voltage, minus the voltage drop across the P-channel MOSFET.

## Soft Start

When the input voltage on AVIN exceeds the UVLO threshold and EN is high, the circuit releases SS and enables the PWM regulator. A capacitor connected to the SS pin and AGND is charged by a $4 \mu \mathrm{~A}$ internal current source, causing the voltage on the capacitor to rise. When this voltage reaches 1.2 V , the output is in regulation. The SS voltage continues to rise to AVIN. The time for the output to reach regulation is given by the following equation:

$$
\begin{equation*}
t(m s)=\frac{C_{S S}(n F)}{(4 \mu A / 1.2 V)} \tag{1}
\end{equation*}
$$

Output overload and short-circuit protection is active during soft-start. When the part is disabled, SS pin is pulled low internally.

## Overload \& Short-Circuit Protection

FAN8060 employs cycle-by-cycle current limiting, which limits current by reducing duty cycle during overload. As the load increases beyond the limit, the output voltage starts to reduce, thereby reducing the FB voltage. When the FB node is half the reference voltage and the COMP node has reached maximum value, short-circuit protection is detected. At that time, both the SS pin and the COMP pin are pulled to ground until the inductor current crosses zero. At that point, both SS and COMP are released for the current to ramp up again. This continues until the short-circuit condition is released.

## Typical Performance Characteristics

$\mathrm{V}_{\text {IN }}=5 \mathrm{~V}$, $\mathrm{V}_{\text {out }}=2.4 \mathrm{~V}$, $\mathrm{L}=3.3 \mu \mathrm{H}, \mathrm{C}_{\mathrm{IN}}=10 \mu \mathrm{~F}$, $\mathrm{C}_{\text {out }}=10 \mu \mathrm{~F}, \mathrm{f}_{\mathrm{S}}=1.2 \mathrm{MHz}, \mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise noted.

## Applications Information

## Refer to Figure 1 for reference designators.

## Output Voltage Setting

The output voltage of the FAN8060 can be set from 1.2 V to $\mathrm{V}_{\mathrm{IN}}$ by an external resistor divider, given by the following equation:
$V_{\text {OUT }}=1.2\left(1+\frac{R_{2}}{R_{3}}\right)$
where, $\mathrm{V}_{\text {оut }}$ equals the output voltage.

## Inductor Selection

Typically, the inductor value is chosen based on ripple current ( $\Delta \mathrm{I}_{\mathrm{L}}$ ), which is chosen between $10 \%$ and $35 \%$ of the maximum DC load. Regulator designs that require fast transient response use a higher ripple-current setting, while regulator designs that require higher efficiency keep ripple current on the low side and operate at a lower switching frequency.

For a given output voltage ripple requirement, L can be calculated by the following equation:

$$
\begin{equation*}
L \geq \frac{V_{\text {OUT }} \cdot(1-D)}{\Delta_{L} \cdot f_{S}} \tag{3}
\end{equation*}
$$

where;
$D=$ Duty ratio $\left(\mathrm{V}_{\mathrm{O}} / \mathrm{V}_{\mathrm{IN}}\right)$;
$\mathrm{f}_{\mathrm{S}}=$ Switching frequency; and
$\Delta I_{\mathrm{L}}=$ Inductor ripple value, typically set to 10\% $35 \%$ of the maximum steady-state load current.

The inductor should have a low DCR to minimize the conduction losses and maximize efficiency. Some recommended inductors are suggested in Table 1:

Table 1. Recommended Inductors ( $\mathbf{3 . 3} \boldsymbol{\mu} \mathrm{H}$ )

| Size[mm2] | DCR | Part Number | Vendor |
| :---: | :---: | :---: | :---: |
| $7 \times 7 \times 3$ | $23 \mathrm{~m} \Omega$ | SLF7032T-3R3 | TDK |
| $5 \times 5 \times 2$ | $60 \mathrm{~m} \Omega$ | LTF5022T-3R3 | TDK |
| $4 \times 4 \times 2$ | $78 \mathrm{~m} \Omega$ | VLCF4020T-3R3 | TDK |
| $2.6 \times 2.8 \times 1.2$ | $130 \mathrm{~m} \Omega$ | VLF3012AT-3R3 | TDK |

## Output Capacitor Selection

The output capacitor is selected based on the needs of the final application and its output ripple requirements. A larger output capacitor value reduces the output ripple voltage. The formula of output ripple $\Delta$ Vout is:

$$
\begin{equation*}
\Delta V_{\text {OUT }} \cong \Delta I_{L}\left(E S R+\frac{1}{8 \cdot C_{\text {OUT }} \cdot f_{S}}\right) \tag{4}
\end{equation*}
$$

where Cout is the output capacitor.
ESR is the equivalent series resistance of the output capacitor.

## Input Capacitor Selection

The input capacitor reduces the RMS current drawn from the input and switching noise from the device. The combined RMS current rating for the input capacitor should be greater than the value calculated by the following equation:

$$
\begin{equation*}
I_{\text {RMS }}=I_{\text {OUTMAX }} \cdot\left(\sqrt{D-D^{2}}\right) \tag{5}
\end{equation*}
$$

where:
$\mathrm{I}_{\mathrm{RMS}}=$ RMS current of the input capacitor; and
loutmax $=$ Maximum output current.
Small, high value, inexpensive, lower-ESR ceramic capacitors are recommended; $10 \mu \mathrm{~F}$ ceramic capacitors with X7R or X5R should be adequate for 1 A applications.

## Loop Compensation

The loop is compensated using a feedback network connected between COMP and AGND. Figure 14 shows a Type-2 compensation network used to stabilize the FAN8060.

Figure 14. Compensation Network
The goal of the compensation design is to shape the frequency response of the converter to achieve high DC gain and fast transient, while maintaining loop stability. FAN8060 employs peak-current-mode control for easy use and fast transient response. Current mode control helps simplify the loop to a one-pole and one zero system.

The DC gain of the voltage feedback loop is given by:

$$
\begin{equation*}
A_{V D C}=R_{L} \cdot G_{C S} \cdot A_{V E A} \cdot \frac{V_{F B}}{V_{O U T}} \tag{6}
\end{equation*}
$$

where:
$A_{v D C}=D C$ gain of the feedback loop;
$\mathrm{R}_{\mathrm{L}}=$ Load resistor value ( $\mathrm{V}_{\text {OUT }} / \mathrm{l}_{\text {out }}$ );
$G_{c s}=$ Current sense gain (3 A/V);
Avea $=$ Error amplifier voltage gain (550 V/V); and
$\mathrm{V}_{\mathrm{FB}}=$ Feedback threshold voltage (1.2 V).

The system pole is calculated by the equation:
$f_{P 1}=\frac{1}{2 \pi \cdot C_{\text {OUT }} \cdot R_{L}}$
The system zero is due to the output capacitor and its ESR. System zero is calculated by the equation:
$f_{z 1}=\frac{1}{2 \pi \cdot C_{\text {OUT }} \cdot E S R}$
The output characteristics of the error (Gm) amplifier are controlled by a series capacitor and resistor network connected at the COMP pin to GND.

The pole is calculated by the following equation:

$$
\begin{equation*}
f_{p 2}=\frac{G_{E A}}{2 \pi \cdot C_{C} \cdot A_{V E A}} \tag{9}
\end{equation*}
$$

where:
$\mathrm{G}_{\mathrm{EA}}=$ Error Amplifier Transconductance (1000 $\mu \mathrm{A} / \mathrm{V}$ ); and
$\mathrm{C}_{\mathrm{C}}=$ compensation capacitor.
Zero is due to the compensation capacitor ( $\mathrm{C}_{\mathrm{C}}$ ) and resistor $\left(\mathrm{R}_{\mathrm{C}}\right)$ calculated by the following equation:

$$
\begin{equation*}
f_{z 2}=\frac{1}{2 \pi \cdot C_{C} \cdot R_{C}} \tag{10}
\end{equation*}
$$

where $R_{C}$ is compensation resistor.
The system crossover frequency ( $\mathrm{f}_{\mathrm{C}}$ ), where the control loop has unity gain, is recommended to be set at $1 / 10^{\text {th }}$ of switching frequency. Generally, higher $f_{c}$ means faster response to load transients, but can result in instability if not properly compensated.
The first step in compensation design is choosing the compensation resistor $\left(\mathrm{R}_{\mathrm{C}}\right)$ to set the crossover frequency by the following equation:

$$
\begin{equation*}
R_{C}=\frac{2 \pi \cdot C_{O U T} \cdot f_{C} \cdot V_{O U T}}{G_{C S} \cdot G_{E A} \cdot V_{F B}} \tag{11}
\end{equation*}
$$

where $V_{F B}$ is reference voltage.
The next step is choosing the compensation capacitor (Cc) to achieve the desired phase margin. For applications with typical inductor values, setting the compensation zero, $\mathrm{f}_{\mathrm{z} 2}$, to below one fourth of the crossover frequency provides sufficient phase margin. Determine the $\left(\mathrm{C}_{\mathrm{C}}\right)$ value by the following equation:

$$
\begin{equation*}
c_{C}=\frac{2}{\pi \cdot R_{C} \cdot f_{C}} \tag{12}
\end{equation*}
$$

Then determine if the second compensation capacitor $\left(C_{A}\right)$ is required. It is required if the ESR zero of the output capacitor is located at less than half of the switching frequency.

$$
\begin{equation*}
\frac{1}{2 \pi \cdot C_{O U T} \cdot E S R}<\frac{f_{S}}{2} \tag{13}
\end{equation*}
$$

If required, add the second compensation capacitor $\left(\mathrm{C}_{\mathrm{A}}\right)$ to set the pole $\mathrm{f}_{\mathrm{P} 3}$ at the location of the ESR zero. Determine $\left(C_{A}\right)$ value by the equation:
$C_{A}=\frac{C_{\text {OUT }} \cdot E S R}{R_{C}}$

## Design Example

Table 2 provides component values for delivering various output voltages with loads up to $1 A$ with $\mathrm{V}_{\mathrm{IN}}$ at $5 \mathrm{~V}( \pm 10 \%$ tolerance).

Table 2. Recommended Feedback and Compensation Values ( $\mathrm{V}_{\mathrm{IN}}=5 \mathrm{~V}$ )

| Vo | $\mathrm{C}_{4}$ | $\mathrm{L}_{1}$ | $\mathrm{R}_{2}$ | $\mathrm{R}_{3}$ | $\mathrm{R}_{1}$ | $\mathrm{C}_{5}$ | $\mathrm{C}_{2}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1.2 V | $10 \mu \mathrm{~F}$ | $3.3 \mu \mathrm{H}$ | Short | Open | $4.7 \mathrm{k} \Omega$ | 1.5 nF | 150 pF |
| 1.5 V |  |  | $2.55 \mathrm{k} \Omega$ | $10.2 \mathrm{k} \Omega$ |  |  |  |
| 1.8 V |  |  | $5.9 \mathrm{k} \Omega$ | $11.8 \mathrm{k} \Omega$ |  |  |  |
| 2.5 V |  |  | $16.2 \mathrm{k} \Omega$ | $15 \mathrm{k} \Omega$ |  |  |  |
| 3.3 V |  |  | $18.7 \mathrm{k} \Omega$ | $10.7 \mathrm{k} \Omega$ |  |  |  |

Figure 15. Recommended Schematic (5 $\mathrm{V}_{\mathrm{IN}}$ to 2.5 V )

## PCB Layout Recommendations

The switching power supply PCB layout needs careful attention and is critical to achieving low losses and clean and stable operation. Although each design is different, below are some general recommendations for a good PCB layout.

- Keep the high-current traces and load connectors as short and wide as possible. These traces consist of VIN, GND, VOUT, and SW.
- Place the input capacitor, the inductor, and the output capacitor as close as possible to the IC terminals.
- Keep the loop area between SW node, inductor, and output capacitors as small as possible; minimizing ground loops to reduce EMI issues.
- Route high-dV/dt signals, such as SW node, away from the error amplifier input/output pins.
- Keep components connected to the FB and COMP pins close to the pins.

Figure 16. Recommended PCB Layout
