

NCP2890, NCV2890

Audio Power Amplifier, 1.0 W

The NCP2890 is an audio power amplifier designed for portable communication device applications such as mobile phone applications. The NCP2890 is capable of delivering 1.0 W of continuous average power to an 8.0 Ω BTL load from a 5.0 V power supply, and 320 mW to a 4.0 Ω BTL load from a 2.6 V power supply.

The NCP2890 provides high quality audio while requiring few external components and minimal power consumption. It features a low-power consumption shutdown mode, which is achieved by driving the SHUTDOWN pin with logic low.

The NCP2890 contains circuitry to prevent from “pop and click” noise that would otherwise occur during turn-on and turn-off transitions.

For maximum flexibility, the NCP2890 provides an externally controlled gain (with resistors), as well as an externally controlled turn-on time (with the bypass capacitor).

Due to its excellent PSRR, it can be directly connected to the battery, saving the use of an LDO.

This device is available in a 9-Pin Flip-Chip CSP (standard –Lead and Lead-Free versions) and a Micro8™ package.

Features

- 1.0 W to an 8.0 Ω BTL Load from a 5.0 V Power Supply
- Excellent PSRR: Direct Connection to the Battery
- “Pop and Click” Noise Protection Circuit
- Ultra Low Current Shutdown Mode
- 2.2 V–5.5 V Operation
- External Gain Configuration Capability
- External Turn-on Time Configuration Capability
- Up to 1.0 nF Capacitive Load Driving Capability
- Thermal Overload Protection Circuitry
- AEC-Q100 Qualified Part Available
- Pb-Free Packages are Available
- NCV Prefix for Automotive and Other Applications Requiring Site and Control Changes

Typical Applications

- Portable Electronic Devices
- PDAs
- Wireless Phones

PIN DESCRIPTION

9-Pin Flip-Chip CSP	Micro8	Type	Symbol	Description
A1	4	I	INM	Negative input of the first amplifier, receives the audio input signal. Connected to the feedback resistor R_f and to the input resistor R_{in} .
A2	5	O	OUTA	Negative output of the NCP2890. Connected to the load and to the feedback resistor R_f .
A3	3	I	INP	Positive input of the first amplifier, receives the common mode voltage.
B1	NA	I	VM_P	Power Analog Ground.
B2	7	I	VM	Core Analog Ground.
B3	6	I	V_p	Positive analog supply of the cell. Range: 2.2 V–5.5 V.
C1	2	I	BYPASS	Bypass capacitor pin which provides the common mode voltage ($V_p/2$).
C2	8	O	OUTB	Positive output of the NCP2890. Connected to the load.
C3	1	I	SHUTDOWN	The device enters in shutdown mode when a low level is applied on this pin.

MAXIMUM RATINGS (Note 1)

Rating	Symbol	Value	Unit	
Supply Voltage	V_p	6.0	V	
Operating Supply Voltage	Op V_p	2.2 to 5.5 V 2.0 V = Functional Only	–	
Input Voltage	V_{in}	–0.3 to $V_{cc} + 0.3$	V	
Max Output Current	I_{out}	500	mA	
Power Dissipation (Note 2)	P_d	Internally Limited	–	
Operating Ambient Temperature	T_A	–40 to +85	°C	
Max Junction Temperature	T_J	150	°C	
Storage Temperature Range	T_{stg}	–65 to +150	°C	
Thermal Resistance Junction-to-Air	$R_{\theta JA}$	230 (Note 3)	°C/W	
ESD Protection	Human Body Model (HBM) (Note 4)	–	8000	V
	Machine Model (MM) (Note 5)	–	>250	

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

- Maximum electrical ratings are defined as those values beyond which damage to the device may occur at $T_A = +25^\circ\text{C}$.
- The thermal shutdown set to 160°C (typical) avoids irreversible damage on the device due to power dissipation. For further information see page 10.
- For the 9-Pin Flip-Chip CSP package, the $R_{\theta JA}$ is highly dependent of the PCB Heatsink area. For example, $R_{\theta JA}$ can equal 195°C/W with 50 mm^2 total area and also 135°C/W with 500 mm^2 . For further information see page 10. The bumps have the same thermal resistance and all need to be connected to optimize the power dissipation.
- Human Body Model, 100 pF discharge through a $1.5\text{ k}\Omega$ resistor following specification JESD22/A114.
- Machine Model, 200 pF discharged through all pins following specification JESD22/A115.

NCP2890, NCV2890

APPLICATION INFORMATION

Detailed Description

The NCP2890 audio amplifier can operate under 2.6 V until 5.5 V power supply. It delivers 320 mW rms output power to 4.0 Ω load ($V_p = 2.6$ V) and 1.0 W rms output power to 8.0 Ω load ($V_p = 5.0$ V).

The structure of the NCP2890 is basically composed of two identical internal power amplifiers; the first one is externally configurable with gain-setting resistors R_{in} and R_f (the closed-loop gain is fixed by the ratios of these resistors) and the second is internally fixed in an inverting unity-gain configuration by two resistors of 20 kΩ. So the load is driven differentially through OUTA and OUTB outputs. This configuration eliminates the need for an output coupling capacitor.

Internal Power Amplifier

The output PMOS and NMOS transistors of the amplifier were designed to deliver the output power of the specifications without clipping. The channel resistance (R_{on}) of the NMOS and PMOS transistors does not exceed 0.6 Ω when they drive current.

The structure of the internal power amplifier is composed of three symmetrical gain stages, first and medium gain stages are transconductance gain stages to obtain maximum bandwidth and DC gain.

Turn-On and Turn-Off Transitions

A cycle with a turn-on and turn-off transition is illustrated with plots that show both single ended signals on the previous page.

In order to eliminate “pop and click” noises during transitions, output power in the load must be slowly established or cut. When logic high is applied to the shutdown pin, the bypass voltage begins to rise exponentially and once the output DC level is around the common mode voltage, the gain is established slowly (50 ms). This way to turn-on the device is optimized in terms of rejection of “pop and click” noises.

The device has the same behavior when it is turned-off by a logic low on the shutdown pin. During the shutdown mode, amplifier outputs are connected to the ground.

When a shutdown low level is applied, it takes 350 ms before the DC output level is tied to Ground. However, as shown on Figure 30, the turn off time of the audio signal is 40 ms.

A theoretical value of turn-on time at 25°C is given by the following formula.

C_{by} : bypass capacitor

R: internal 300 k resistor with a 25% accuracy

$$T_{on} = 0.95 * R * C_{by} \text{ (285 ms with } C_{by} = 1 \mu\text{F)}$$

If a faster turn on time is required then a lower bypass capacitor can be used. The other option is to use NCP2892 which offers 100 ms with 1 μF bypass capacitor.

Shutdown Function

The device enters shutdown mode when shutdown signal is low. During the shutdown mode, the DC quiescent current of the circuit does not exceed 100 nA.

Current Limit Circuit

The maximum output power of the circuit ($P_{orms} = 1.0$ W, $V_p = 5.0$ V, $R_L = 8.0$ Ω) requires a peak current in the load of 500 mA.

In order to limit the excessive power dissipation in the load when a short-circuit occurs, the current limit in the load is fixed to 800 mA. The current in the four output MOS transistors are real-time controlled, and when one current exceeds 800 mA, the gate voltage of the MOS transistor is clipped and no more current can be delivered.

Thermal Overload Protection

Internal amplifiers are switched off when the temperature exceeds 160°C, and will be switched on again only when the temperature decreases fewer than 140°C.

The NCP2890 is unity-gain stable and requires no external components besides gain-setting resistors, an input coupling capacitor and a proper bypassing capacitor in the typical application.

The first amplifier is externally configurable (R_f and R_{in}), while the second is fixed in an inverting unity gain configuration.

The differential-ended amplifier presents two major advantages:

- The possible output power is four times larger (the output swing is doubled) as compared to a single-ended amplifier under the same conditions.
- Output pins (OUTA and OUTB) are biased at the same potential $V_p/2$, this eliminates the need for an output coupling capacitor required with a single-ended amplifier configuration.

The differential closed loop-gain of the amplifier is given by $A_{vd} = 2 * \frac{R_f}{R_{in}} = \frac{V_{orms}}{V_{inrms}}$.

Output power delivered to the load is given by $P_{orms} = \frac{(V_{opeak})^2}{2 * R_L}$ (V_{opeak} is the peak differential output voltage).

When choosing gain configuration to obtain the desired output power, check that the amplifier is not current limited or clipped.

The maximum current which can be delivered to the load is 500 mA $I_{opeak} = \frac{V_{opeak}}{R_L}$.

NCP2890, NCV2890

Gain-Setting Resistor Selection (R_{in} and R_f)

R_{in} and R_f set the closed-loop gain of the amplifier.

In order to optimize device and system performance, the NCP2890 should be used in low gain configurations.

The low gain configuration minimizes THD + noise values and maximizes the signal to noise ratio, and the amplifier can still be used without running into the bandwidth limitations.

A closed loop gain in the range from 2 to 5 is recommended to optimize overall system performance.

An input resistor (R_{in}) value of 22 k Ω is realistic in most of applications, and doesn't require the use of a too large capacitor C_{in} .

Input Capacitor Selection (C_{in})

The input coupling capacitor blocks the DC voltage at the amplifier input terminal. This capacitor creates a high-pass filter with R_{in} , the cut-off frequency is given by

$$f_c = \frac{1}{2 * \pi * R_{in} * C_{in}}$$

The size of the capacitor must be large enough to couple in low frequencies without severe attenuation. However a large input coupling capacitor requires more time to reach its quiescent DC voltage ($V_p/2$) and can increase the turn-on pops.

An input capacitor value between 0.1 μ and 0.39 μ F performs well in many applications (With $R_{in} = 22$ K Ω).

Bypass Capacitor Selection (C_{by})

The bypass capacitor C_{by} provides half-supply filtering and determines how fast the NCP2890 turns on.

This capacitor is a critical component to minimize the turn-on pop. A 1.0 μ F bypass capacitor value ($C_{in} = < 0.39$ μ F) should produce clickless and popless shutdown transitions. The amplifier is still functional with a 0.1 μ F capacitor value but is more susceptible to "pop and click" noises.

Thus, a 1.0 μ F bypassing capacitor is recommended.
