

Flyback, Boost, Forward PWM Controller

NCP1294

The NCP1294 fixed frequency feed forward voltage mode PWM controller contains all of the features necessary to be configured in a Flyback, Boost or Forward topology. This PWM controller has been optimized for high frequency primary side control operation. In addition, this device includes such features as: Soft-Start, accurate duty cycle limit control, less than 50µA startup current, over and undervoltage protection, and bidirectional synchronization. The NCP1294 is available in a 16 lead SOIC narrow surface mount package.

Features

- 1.0 MHz Frequency Capability
- Fixed Frequency Voltage Mode Operation, with Feed Forward
- Thermal Shutdown
- Undervoltage Lock-Out
- Accurate Programmable Max Duty Cycle Limit
- 1.0 A Sink/Source Gate Drive
- Programmable Pulse-By-Pulse Overcurrent Protection
- Leading Edge Current Sense Blanking
- 75 ns Shutdown Propagation Delay
- Programmable Soft-Start
- Undervoltage Protection
- Overvoltage Protection with Programmable Hysteresis
- Bidirectional Synchronization
- 25 ns GATE Rise and Fall Time (1.0 nF Load)
- 3.3 V 3% Reference Voltage Output
- These Devices are Pb-Free, Halogen Free/BFR Free and are RoHS Compliant

NCP1294

PACKAGE PIN DESCRIPTION

Package Pin #	Pin Symbol	Function
1	GATE	External power switch driver with 1.0 A peak capability. Rail to rail output occurs when the capacitive load is between 470 pF and 10 nF.
2	I _{SENSE}	Current sense comparator input.
3	SYNC	Bidirectional synchronization. Locks to highest frequency.
4	FF	PWM ramp.
5	UV	Undervoltage protection monitor.
6	OV	Overvoltage protection monitor.
7	R _T C _T	Timing resistor R _T and capacitor C _T determine oscillator frequency and maximum duty cycle, D _{MAX} .
8	I _{SET}	Voltage at this pin sets pulse-by-pulse overcurrent threshold.
9	V _{FB}	Feedback voltage input. Connected to the error amplifier inverting input.
10	COMP	Error amplifier output.
11	SS	Charging external capacitor restricts error amplifier output voltage during the power up or fault conditions.
12	LGND	Logic ground.
13	V _{REF}	3.3 V reference voltage output. Decoupling capacitor can be selected from 0.01- μ F to 10 μ F.
14	V _{CC}	Logic supply voltage.
15	PGND	Output power stage ground.
16	V _C	Output power stage supply voltage.

APPLICATION INFORMATION

THEORY OF OPERATION

Feed Forward Voltage Mode Control

In conventional voltage mode control, the ramp signal has fixed rising and falling slope. The feedback signal is derived solely from the output voltage. Consequently, voltage mode control has inferior line regulation and audio susceptibility.

Feed forward voltage mode control derives the ramp signal from the input line, as shown in Figure 3. Therefore, the ramp of the slope varies with the input voltage. At the start of each switch cycle, the capacitor connected to the FF pin is charged through a resistor connected to the input voltage. Meanwhile, the Gate output is turned on to drive an external power switching device. When the FF pin voltage reaches the error amplifier output V_{COMP} , the PWM comparator turns off the Gate, which in turn opens the external switch. Simultaneously, the FF capacitor is quickly discharged to 0.3 V.

Overall, the dynamics of the duty cycle are controlled by both input and output voltages. As illustrated in Figure 4, with a fixed input voltage the output voltage is regulated solely by the error amplifier. For example, an elevated output voltage reduces V_{COMP} which in turn causes duty cycle to decrease. However, if the input voltage varies, the slope of the ramp signal will react immediately which provides a much improved line transient response. As an example shown in Figure 5, when the input voltage goes up, the rising edge of the ramp signal increases which reduces duty cycle to counteract the change.

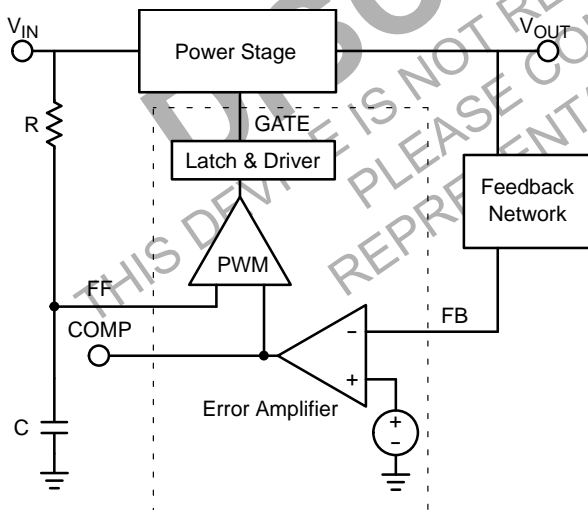

Figure 3. Feed Forward Voltage Mode Control

The feed forward feature can also be employed to provide a volt-second clamp, which limits the maximum product of input voltage and turn on time. This clamp is used in circuits, such as Forward and Flyback converter, to prevent the transformer from saturating. Calculations used in the design of the volt-second clamp are presented in the Design Guidelines section.

Figure 4. Pulse Width Modulated by Output Current with Constant Input Voltage

Figure 5. Pulse Width Modulated by Input Voltage with Constant Output Current

Powering the IC & UVL

The Undervoltage Lockout (UVL) comparator has two voltage references; the start and stop thresholds. During power-up, the UVL comparator disables V_{REF} (which in-turn disables the entire IC) until the controller reaches its V_{CC} start threshold. During power-down, the UVL comparator allows the controller to operate until the V_{CC} stop threshold is reached. The NCP1294 requires only 50 μA during startup. The output stage is held at a low impedance state in lock out mode.

During power up and fault conditions, the Soft-Start clamps the Comp pin voltage and limits the duty cycle. The power up transition tends to generate temporary duty cycles much greater than the steady state value due to the low output voltage. Consequently, excessive current stresses often take place in the system. Soft-Start technique alleviates this problem by gradually releasing the clamp on the duty cycle to eliminate the in-rush current. The duration

of the Soft-Start can be programmed through a capacitance connected to the SS pin. The constant charging current to the SS pin is 50 μ A (typ).

The V_{REF} (ok) comparator monitors the 3.3 V V_{REF} output and latches a fault condition if V_{REF} falls below 3.1 V. The fault condition may also be triggered when the OV pin voltage rises above 2.0 V or the UV pin voltage falls below 1.0 V. The undervoltage comparator has a built-in hysteresis of 75 mV (typ). The hysteresis for the OV comparator is programmable through a resistor connected to the OV pin. When an OV condition is detected, the overvoltage hysteresis current of 12.5 μ A (typ) is sourced from the pin.

In Figure 6, the fault condition is triggered by pulling the UV pin to the ground. Immediately, the SS capacitor is discharged with 5.0 μ A of current (typ) and the GATE output is disabled until the SS voltage reaches the discharge voltage of 0.3 V (typ). The IC starts the Soft-Start transition again if the fault condition has recovered as shown in Figure 6. However, if the fault condition persists, the SS voltage will stay at 0.1 V until the removal of the fault condition.

Figure 6. The Fault Condition Is Triggered when the UV Pin Voltage Falls Below 1.0 V. The Soft-Start Capacitor Is Discharged and the GATE Output Is Disabled. CH2: Envelop of GATE Output, CH3: SS Pin with 0.01 μ F Capacitor, CH4: UV Pin

Current Sense and Overcurrent Protection

The current can be monitored by the I_{SENSE} pin to achieve pulse by pulse current limit. Various techniques, such as a using current sense resistor or current transformer, can be adopted to derive current signals. The voltage of the I_{SET} pin sets the threshold for maximum current. As shown in Figure 7, when the I_{SENSE} pin voltage exceeds the I_{SET} voltage, the current limit comparator will reset the GATE latch flip-flop to terminate the GATE pulse.

Figure 7. The GATE Output Is Terminated When the I_{SENSE} Pin Voltage Reaches the Threshold Set By the I_{SET} Pin. CH2: I_{SENSE} Pin, CH4: I_{SET} Pin, CH3: GATE Pin

The current sense signal is prone to leading edge spikes caused by the switching transition. A RC low-pass filter is usually applied to the current signals to avoid premature triggering. However, the low pass filter will inevitably change the shape of the current pulse and also add cost. The NCP1294 uses leading edge blanking circuitry that blocks out the first 150 ns (typ) of each current pulse. This removes the leading edge spikes without altering the current waveform. The blanking is disabled during Soft-Start and when the V_{COMP} is saturated high so that the minimum on-time of the controller does not have the additional blanking period. The max SS detect comparator keeps the blanking function disabled until SS charges fully. The output of the max Duty Cycle detector goes high when the error amplifier output gets saturated high, indicating that the output voltage has fallen well below its regulation point and the power supply may be underload stress.

Oscillator and Synchronization

The switching frequency is programmable through a RC network connected to the R_{TC_T} Pin. As shown in Figure 8, when the R_{TC_T} pin reaches 2.0 V, the capacitor is discharged by a 1.0 mA current source and the Gate signal is disabled. When the R_{TC_T} pin decreases to 1.0 V, the Gate output is turned on and the discharge current is removed to let the R_{TC_T} pin ramp up. This begins a new switching cycle. The C_T charging time over the switch period sets the maximum duty cycle clamp which is programmable through the R_T value as shown in the Design Guidelines. At the beginning of each switching cycle, the SYNC pin generates a 2.5 V, 320 ns (typ) pulse. This pulse can be utilized to synchronize other power supplies.

DESIGN GUIDELINES

Figure 8. The SYNC Pin Generates a Sync Pulse at the Beginning of Each Switching Cycle. CH2: GATE Pin, CH3: R_TC_T, CH4: SYNC Pin

Figure 9. Operation with External Sync. CH2: SYNC Pin, CH3: GATE Pin, CH4: R_TC_T Pin

An external pulse signal can feed to the bidirectional SYNC pin to synchronize the switch frequency. For reliable operation, the sync frequency should be approximately 20% higher than free running IC frequency. As show in Figure 9, when the SYNC pin is triggered by an incoming signal, the IC immediately discharges C_T. The GATE signal is turned on once the R_TC_T pin reaches the valley voltage. Because of the steep falling edge, this valley voltage falls below the regular 1.0 V threshold. However, the R_TC_T pin voltage is then quickly raised by a clamp. When the R_TC_T pin reaches the 0.95 V (typ) Valley Clamp Voltage, the clamp is disconnected after a brief delay and C_T is charged through R_T.

Switch Frequency and Maximum Duty Cycle Calculations

Oscillator timing capacitor, C_T, is charged by V_{REF} through R_T and discharged by an internal current source. During the discharge time, the internal clock signal sets the Gate output to the low state, thus providing a user selectable maximum duty cycle clamp. Charge and discharge times are determined by following general formulas;

$$t_C = R_T C_T \ln \left(\frac{V_{REF} - V_{VALLEY}}{V_{REF} - V_{PEAK}} \right)$$

$$t_d = R_T C_T \ln \left(\frac{V_{REF} - V_{PEAK} - I_d R_T}{V_{REF} - V_{VALLEY} - I_d R_T} \right)$$

where:

- t_C = charging time;
- t_d = discharging time;
- V_{VALLEY} = valley voltage of the oscillator;
- V_{PEAK} = peak voltage of the oscillator.

Substituting in typical values for the parameters in the above formulas, V_{REF} = 3.3 V, V_{VALLEY} = 1.0 V, V_{PEAK} = 2.0 V, I_d = 1.0 mA:

$$t_C = 0.57 R_T C_T$$

$$t_d = R_T C_T \ln \left(\frac{1.3 - 0.001 R_T}{2.3 - 0.001 R_T} \right)$$

$$D_{max} = \frac{0.57}{0.57 + \ln \left(\frac{1.3 - 0.001 R_T}{2.3 - 0.001 R_T} \right)}$$

It is noticed from the equation that for the oscillator to function properly, R_T has to be greater than 2.3 k.

Select RC for Feed Forward Ramp

If the line voltage is much greater than the FF pin Peak Voltage, the charge current can be treated as a constant and is equal to V_{IN}/R. Therefore, the volt-second value is determined by:

$$V_{IN} \times T_{ON} = (V_{COMP} - V_{FF(d)}) \times R \times C$$

where:

- V_{COMP} = COMP pin voltage;
- V_{FF(d)} = FF pin discharge voltage.

As shown in the equation, the volt-second clamp is set by the V_{COMP} clamp voltage which is equal to 1.8 V. In Forward or Flyback circuits, the volt-second clamp value is designed to prevent transformers from saturation.

In a buck or forward converter, volt-second is equal to

$$V_{IN} \times T_{ON} = \left(\frac{V_{OUT} \times T_S}{n} \right)$$

n = transformer turns ratio, which is a constant determined by the regulated output voltage, switching period and transformer turns ration (use 1.0 for buck converter). It is interesting to notice from the aforementioned two equations

Figure 10. Typical Performance Characteristics, Oscillator Frequency vs. C_T

Figure 11. Typical Performance Characteristics, Oscillator Duty Cycle vs. R_T

that during steady state, V_{COMP} doesn't change for input voltage variations. This intuitively explains why FF voltage mode control has superior line regulation and line transient response. Knowing the nominal value of V_{IN} and T_{ON} , one can also select the value of RC to place V_{COMP} at the center of its dynamic range.

Select Feedback Voltage Divider

As shown in Figure 12, the voltage divider output feeds to the FB pin, which connects to the inverting input of the error amplifier. The non-inverting input of the error amplifier is connected to a 1.27 V (typ) reference voltage. The FB pin has an input current which has to be considered for accurate DC outputs. The following equation can be used to calculate the R_1 and R_2 value

$$\left(\frac{R_2}{R_1 + R_2}\right)V_{OUT} = 1.27 - \nabla$$

where ∇ is the correction factor due to the existence of the FB pin input current I_{er} .

$$\nabla = (R_i + R_1/R_2)I_{er}$$

R_i = DC resistance between the FB pin and the voltage divider output.

I_{er} = V_{FB} input current, 1.3 μA typical.

Design Voltage Dividers for OV and UV Detection

In Figure 13, the voltage divider uses three resistors in series to set OV and UV threshold seen from the input voltage. The values of the resistors can be calculated from the following three equations, where the third equation is derived from OV hysteresis requirement.

$$V_{IN(LOW)} \times \left(\frac{R_2 + R_3}{R_2 + R_3 + R_1}\right) = 1.0 \text{ V} \quad (A)$$

$$V_{IN(HIGH)} \times \left(\frac{R_3}{R_2 + R_3 + R_1}\right) = 2.0 \text{ V} \quad (B)$$

$$12.5 \mu A \times (R_1 + R_2) = V_{HYST} \quad (C)$$

where:

$V_{IN(LOW)}$, $V_{IN(HIGH)}$ = input voltage OV and UV threshold;

V_{HYST} = OV hysteresis seen at V_{IN}

It is self-evident from equation A and B that to use this design, $V_{IN(HIGH)}$ has to be two times greater than $V_{IN(LOW)}$. Otherwise, two voltage dividers have to be used to program OV and UV separately.

SOLDERING FOOTPRINT*

GENERIC
MARKING DIAGRAM*

- XXXX = Specific Device Code
- A = Assembly Location
- L = Wafer Lot
- Y = Year
- W = Work Week
- G or ■ = Pb-Free Package

*This information is generic. Please refer to device data sheet for actual part marking. Pb-Free indicator, "G" or microdot "■", may or may not be present. Some products may not follow the Generic Marking.

*For additional information on our Pb-Free strategy and soldering details, please download the onsemi Soldering and Mounting Techniques Reference Manual, SOLDERRM/D.

DESCRIPTION:	TSSOP-16	PAGE 1 OF 1

onsemi and onsemi are trademarks of Semiconductor Components Industries, LLC dba onsemi or its subsidiaries in the United States and/or other countries. onsemi reserves the right to make changes without further notice to any products herein. onsemi makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does onsemi assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation special, consequential or incidental damages. onsemi does not convey any license under its patent rights nor the rights of others.

onsemi, **Onsemi**, and other names, marks, and brands are registered and/or common law trademarks of Semiconductor Components Industries, LLC dba "**onsemi**" or its affiliates and/or subsidiaries in the United States and/or other countries. **onsemi** owns the rights to a number of patents, trademarks, copyrights, trade secrets, and other intellectual property. A listing of **onsemi**'s product/patent coverage may be accessed at www.onsemi.com/site/pdf/Patent-Marking.pdf. **onsemi** reserves the right to make changes at any time to any products or information herein, without notice. The information herein is provided "as-is" and **onsemi** makes no warranty, representation or guarantee regarding the accuracy of the information, product features, availability, functionality, or suitability of its products for any particular purpose, nor does **onsemi** assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation special, consequential or incidental damages. Buyer is responsible for its products and applications using **onsemi** products, including compliance with all laws, regulations and safety requirements or standards, regardless of any support or applications information provided by **onsemi**. "Typical" parameters which may be provided in **onsemi** data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. **onsemi** does not convey any license under any of its intellectual property rights nor the rights of others. **onsemi** products are not designed, intended, or authorized for use as a critical component in life support systems or any FDA Class 3 medical devices or medical devices with a same or similar classification in a foreign jurisdiction or any devices intended for implantation in the human body. Should Buyer purchase or use **onsemi** products for any such unintended or unauthorized application, Buyer shall indemnify and hold **onsemi** and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that **onsemi** was negligent regarding the design or manufacture of the part. **onsemi** is an Equal Opportunity/Affirmative Action Employer. This literature is subject to all applicable copyright laws and is not for resale in any manner.
