

Integrated Driver and MOSFET

NCP402045

PQFN31 5x5, 0.5P
Case 483BR

Description

The NCP402045 integrates a MOSFET driver, high-side MOSFET and low-side MOSFET into a single package.

The driver and MOSFETs have been optimized for high-current DC-DC buck power conversion applications. The NCP402045 integrated solution greatly reduces package parasitics and board space compared to a discrete component solution.

Features

- Capable of Average Currents up to 45 A
- Capable of Switching at Frequencies up to 2 MHz
- Capable of Peak Currents (10 ms) up to 75 A
- Compatible with 3.3 V or 5 V PWM Input
- Responds Properly to 3-level PWM Inputs
- Option for Zero Cross Detection with 3-level PWM
- Internal Bootstrap Diode
- Undervoltage Lockout
- Supports Intel® IMVP9.1/9.2 Low Power Features
- Thermal Warning output
- Thermal Shutdown

Applications

- Notebook, Tablet PC and Ultrabook
- Graphic Card
- Desktop and All-in-One Computers, V-Core and Non-V-Core Converters
- High-Current DC-DC Point-of-Load Converters

NCP402045

Table 1. PIN LIST AND DESCRIPTIONS

Pin No.	Symbol	Description
1	PWM	PWM Control Input and Zero Current Detection Enable
2	SMOD#	Skip Mode pin. 3-state input (see Table 1 LOGIC TABLE): SMOD# = High → State of PWM determine whether the NCP402045 performs ZCD or not. SMOD# = Mid → Connects PWM to internal resistor divider placing a bias voltage on PWM pin. Otherwise, logic is equivalent to SMOD# in the high state. SMOD# = Low → Placing PWM into mid-state pulls GH and GL low without delay. There is an internal pull-up resistor to VCC on this pin.
3	VCC	Control Power Supply Input
4, 32	CGND, AGND	Signal Ground (pin 4 and pad 32 are internally connected)
5	BOOT	Bootstrap Voltage
6	nc	Open pin (not used)
7	PHASE	Bootstrap Capacitor Return
8–11	VIN	Conversion Supply Power Input
12–15, 28	PGND	Power Ground
16–26	VSW	Switch Node Output
27, 33	GL	Low Side FET Gate Access (pin 27 and pad 33 are internally connected)
29	VCCD	Driver Power Supply Input
30	DISB#	Output disable pin. When this pin is pulled to a logic high level, the driver is enabled. There is an internal pull-down resistor on this pin.
31	THWN	Thermal warning indicator. This is an open-drain output. When the temperature at the driver die reaches T_{THWN} , this pin is pulled low.

NCP402045

Table 2. ABSOLUTE MAXIMUM RATINGS (Electrical Information – all signals referenced to PGND unless noted otherwise)

Pin Name/Parameter	Min	Max	Unit
VCC, VCCD	-0.3	6.5	V
VIN	-0.3	30	V
BOOT (DC)	-0.3	35	V
BOOT (< 20 ns)	-0.3 wrt/VSW	40	V
BOOT to PHASE (DC)	-0.3	6.5	V
VSW, PHASE (DC)	-0.3	30	V
VSW (< 5 ns)	-5	37	V
PHASE (< 5 ns)	-10	37	V
All Other Pins	-0.3	$V_{VCC} + 0.3$	V

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

Table 3. THERMAL INFORMATION

Rating	Symbol	Value	Unit
Thermal Resistance (under On Semi SPS Thermal Board)	θ_{JA}	12.4	°C/W
	θ_{J-PCB}	1.8	°C/W
Operating Junction Temperature Range (Note 1)	T_J	-40 to +150	°C
Operating Ambient Temperature Range	T_A	-40 to +125	°C
Maximum Storage Temperature Range	T_{STG}	-55 to +150	°C
Maximum Power Dissipation		10.5	W
Moisture Sensitivity Level	MSL	1	

1. The maximum package power dissipation must be observed.
2. JESD 51-5 (1S2P Direct-Attach Method) with 0 LFM
3. JESD 51-7 (1S2P Direct-Attach Method) with 0 LFM

Table 4. RECOMMENDED OPERATING CONDITIONS

Parameter	Pin Name	Conditions	Min	Typ	Max	Unit
Supply Voltage Range	VCC, VCCD		4.5	5.0	5.5	V
Conversion Voltage	VIN		4.5	12	20	V
Continuous Output Current		$F_{SW} = 1 \text{ MHz}, V_{IN} = 12 \text{ V}, V_{OUT} = 1.0 \text{ V}, T_A = 25^\circ\text{C}$	-	-	40	A
		$F_{SW} = 300 \text{ kHz}, V_{IN} = 12 \text{ V}, V_{OUT} = 1.0 \text{ V}, T_A = 25^\circ\text{C}$	-	-	45	A
Peak Output Current		$F_{SW} = 500 \text{ kHz}, V_{IN} = 12 \text{ V}, V_{OUT} = 1.0 \text{ V},$ Duration = 10 ms, Period = 1 s, $T_A = 25^\circ\text{C}$	-	-	75	A
Junction Temperature			-40	-	125	°C

Functional operation above the stresses listed in the Recommended Operating Ranges is not implied. Extended exposure to stresses beyond the Recommended Operating Ranges limits may affect device reliability.

APPLICATIONS INFORMATION

Theory of Operation

The NCP402045 is an integrated driver and MOSFET module designed for use in a synchronous buck converter topology. The NCP402045 supports numerous application control definitions including ZCD (Zero Current Detect) and alternately PWM Tristate control. A PWM input signal is required to control the drive signals to the high-side and low-side integrated MOSFETs.

Low-Side Driver

The low-side driver drives an internal, ground-referenced low- $R_{DS(on)}$ N-Channel MOSFET. The voltage supply for the low-side driver is internally connected to the VCCD and PGND pins.

High-Side Driver

The high-side driver drives an internal, floating low- $R_{DS(on)}$ N-channel MOSFET. The gate voltage for the high side driver is developed by a bootstrap circuit referenced to Switch Node (VSW and PHASE) pins.

The bootstrap circuit is comprised of the integrated diode and an external bootstrap capacitor and resistor. When the NCP402045 is starting up, the VSW pin is at ground, allowing the bootstrap capacitor to charge up to VCCD through the bootstrap diode (see Figure 1). When the PWM input is driven high, the high-side driver turns on the high-side MOSFET using the stored charge of the bootstrap capacitor. As the high-side MOSFET turns on, the voltage at the VSW and PHASE pins rises. When the high-side MOSFET is fully turned on, the switch node settles to VIN and the BST pin settles to VIN + VCCD (excluding parasitic ringing).

Bootstrap Circuit

The bootstrap circuit relies on an external charge storage capacitor (C_{BST}) and an integrated diode to provide current to the HS Driver. A multi-layer ceramic capacitor (MLCC) with a value greater than 100 nF should be used as the

bootstrap capacitor. An optional 1 to 4 Ω resistor in series with the bootstrap capacitor decreases the VSW overshoot.

Power Supply Decoupling

The NCP402045 sources relatively large currents into the MOSFET gates. In order to maintain a constant and stable supply voltage (VCCD) a low-ESR capacitor should be placed near the power and ground pins. A multi-layer ceramic capacitor (MLCC) between 1 μ F and 4.7 μ F is typically used.

A separate supply pin (VCC) is used to power the analog and digital circuits within the driver. A 1 μ F ceramic capacitor should be placed on this pin in close proximity to the NCP402045. It is good practice to separate the VCC and VCCD decoupling capacitors with a resistor (10 Ω typical) to avoid coupling driver noise to the analog and digital circuits that control the driver function (see Figure 1).

Safety Timer and Overlap Protection Circuit

It is important to avoid cross-conduction of the two MOSFETs which could result in a decrease in the power conversion efficiency or damage to the device.

The NCP402045 prevents cross-conduction by monitoring the status of the MOSFETs and applying the appropriate amount of non-overlap (NOL) time (the time between the turn-off of one MOSFET and the turn-on of the other MOSFET). When the PWM input pin is driven high, the gate of the low-side MOSFET (LSGATE) goes low after a propagation delay (t_{pdIGL}). The time it takes for the low-side MOSFET to turn off is dependent on the total charge on the low-side MOSFET gate.

The NCP402045 monitors the gate voltage of both MOSFETs and the switch node voltage to determine the conduction status of the MOSFETs. Once the low-side MOSFET is turned off an internal timer delays (t_{pdHG}) the turn-on of the high-side MOSFET. When the PWM input pin goes low, the gate of the high-side MOSFET (HSGATE) goes low after the propagation delay (t_{pdIGH}). The time to turn off the high-side MOSFET (t_{fGH}) is dependent on the total gate charge of the high-side MOSFET. A timer is triggered once the high-side MOSFET stops conducting, to delay (t_{pdHGL}) the turn-on of the low-side MOSFET.

Zero Current Detect

The Zero Current Detect PWM (ZCD_PWM) mode is enabled when SMOD# is high (see Tables 6 and 8).

With PWM set to > VPWM_HI, GL goes low and GH goes high after the non-overlap delay. When PWM is driven to < VPWM_HI and to > VPWM_LO, GL goes high after the non-overlap delay, and stays high for the duration of the ZCD blanking timer (T_{ZCD_BLANK}) and an 80 ns de-bounce timer. Once this timer expires, VSW is monitored for zero current detection, and GL is pulled low once zero current is detected. The threshold on VSW to determine zero current undergoes an auto-calibration cycle every time DISB# is brought from low to high. This auto-calibration cycle typically takes 25 μ s to complete.

PWM Input

The PWM Input pin is a tri-state input used to control the HS MOSFET ON/OFF state. It also determines the state of the LS MOSFET. See Table 6 for logic operation. The PWM in some cases must operate with frequency programming resistances to ground. These resistances can range from 10 k Ω to 300 k Ω depending on the application. When SMOD# is set to > VSMOD#_HI or to < VSMOD#_LO, the input impedance to the PWM input is very high in order to avoid interferences with controllers that must use programming resistances on the PWM pin.

If SMOD# is set to < VSMOD#_HI and > VSMOD#_LO (Mid-State), the PWM pin undriven default voltage is set to Mid-State with internal divider resistances.

Disable Input (DISB#)

The DISB# pin is used to disable the GH to the High-Side FET to prevent power transfer. The pin has a pull-down resistance to force a disabled state when it is left unconnected. DISB# can be driven from the output of a logic device or set high with a pull-up resistance to VCC.

Low Power Mode

The NCP402045 offers a low power mode when PWM is at mid-state for $> T_{LPM_ENT_DL}$. The device will remain in this state until PWM has changed state + $T_{LPM_EX_DL}$.

VCC Undervoltage Lockout

The VCC pin is monitored by an Undervoltage Lockout Circuit (UVLO). VCC voltage above the rising threshold enables the NCP402045.

Table 7. UVLO/DISB# LOGIC TABLE

UVLO	DISB#	Driver State
L	X	Disabled (GH = GL = 0)
H	L	Disabled (GH = GL = 0)
H	H	Enabled (See Table 6)
H	Open	Disabled (GH = GL = 0)

When powering up, the power stage will sense the voltage of the switch node; if it is higher than Output Overvoltage Trip Threshold at Startup, a PreOVP protection will be triggered sending the IC into a latched off state: DISB# will be pulled low by its active pulldown and the LS FET will be turned on. This fault is released once VCC power is cycled and no fault is sensed. This fault is only active between POR and UVLO rising.

Thermal Warning/Thermal Shutdown Output

The THWN pin is an open drain output. When the temperature of the driver exceeds T_{THWN} , the THWN pin is pulled low indicating a thermal warning. At this point, the part continues to function normally. When the temperature drops T_{THWN_HYS} below T_{THWN} , the THWN pin goes high. If the driver temperature exceeds T_{THDN} , the part enters thermal shutdown and turns off both MOSFETs. Once the temperature falls T_{THDN_HYS} below T_{THDN} , the part resumes normal operation.

Skip Mode Input (SMOD#)

The SMOD# tri-state input pin has an internal pull-up resistance to VCC. When driven low, the SMOD# pin enables the low side synchronous MOSFET to operate independently of the internal ZCD function. When the SMOD# pin is set low while PWM is in the mid-state, the low side MOSFET is disabled to allow discontinuous mode operation.

The NCP402045 has the capability of internally connecting a resistor divider to the PWM pin. To engage this mode, SMOD# needs to be placed into mid-state. While in SMOD# mid-state, the IC logic is equivalent to SMOD# being in the high state.

NOTES: If the Zero Current Detect circuit detects zero current after the ZCD Wait timer period, the GL is driven low by the Zero Current Detect signal.
 If the Zero Current Detect circuit detects zero current before the ZCD Wait timer period expires, the Zero Current detect signal is ignored and the GL is driven low at the end of the ZCD Wait timer period.

Figure 17. PWM Timing Diagram

NCP402045

For Use with Controllers with 3-State PWM and No Zero Current Detection Capability:

Table 8. LOGIC TABLE – 3-STATE PWM CONTROLLERS WITH NO ZCD

PWM	SMOD#	GH (Not a Pin)	GL
H	H/M	ON	OFF
M	H/M	OFF	ZCD
L	H/M	OFF	ON

This section describes operation with controllers that are capable of 3 states in their PWM output and relies on the NCP402045 to conduct zero current detection during discontinuous conduction mode (DCM).

The SMOD# pin needs to either be set to 5 V or left disconnected. The NCP402045 has an internal pull-up resistor that connects to VCC that sets SMOD# to the logic high state if this pin is disconnected.

To operate the buck converter in continuous conduction mode (CCM), PWM needs to switch between the logic high

and low states. To enter into DCM, PWM needs to be switched to the mid-state.

Whenever PWM transitions to mid-state, GH turns off and GL turns on. GL stays on for the duration of the de-bounce timer and ZCD blanking timers. Once these timers expire, the NCP402045 monitors the VSW voltage and turns GL off when VSW exceeds the ZCD threshold voltage. By turning off the LS FET, the body diode of the LS FET allows any positive current to go to zero but prevents negative current from conducting.

Figure 18. Timing Diagram – 3-State PWM Controller, No ZCD

NCP402045

For Use with Controllers with 3-state PWM and Zero Current Detection Capability:

Table 9. LOGIC TABLE – 3-STATE PWM CONTROLLERS WITH ZCD

PWM	SMOD#	GH (Not a Pin)	GL
H	L	ON	OFF
M	L	OFF	OFF
L	L	OFF	ON

This section describes operation with controllers that are capable of 3 PWM output levels and have zero current detection during discontinuous conduction mode (DCM).

The SMOD# pin needs to be pulled low (below V_{SMOD_LO}).

To operate the buck converter in continuous conduction mode (CCM), PWM needs to switch between the logic high

and low states. During DCM, the controller is responsible for detecting when zero current has occurred, and then notifying the NCP402045 to turn off the LS FET. When the controller detects zero current, it needs to set PWM to mid-state, which causes the NCP402045 to pull both GH and GL to their off states without delay.
