Voltage Regulator - Adjustable Output, Negative

1.5 A

LM337

The LM337 is an adjustable 3–terminal negative voltage regulator capable of supplying in excess of 1.5 A over an output voltage range of −1.2 V to −37 V. This voltage regulator is exceptionally easy to use and requires only two external resistors to set the output voltage. Further, it employs internal current limiting, thermal shutdown and safe area compensation, making it essentially blow–out proof.

The LM337 serves a wide variety of applications including local, on card regulation. This device can also be used to make a programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the LM337 can be used as a precision current regulator.

Features

• Output Current in Excess of 1.5 A
• Output Adjustable between −1.2 V and −37 V
• Internal Thermal Overload Protection
• Internal Short Circuit Current Limiting Constant with Temperature
• Output Transistor Safe–Area Compensation
• Floating Operation for High Voltage Applications
• Eliminates Stocking many Fixed Voltages
• Available in Surface Mount D²PAK and Standard 3–Lead Transistor Package
• These Devices are Pb–Free and are RoHS Compliant

ORDERING INFORMATION

See detailed ordering and shipping information in the package dimensions section on page 8 of this data sheet.

Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

1. T_{low} to T_{high} = 0°C to +125°C, for LM337T, D2T. T_{low} to T_{high} = -40°C to +125°C, for LM337BT, BD2T.
2. I_{max} = 1.5 A, P_{max} = 20 W
3. Load and line regulation are specified at constant junction temperature. Change in V_O because of heating effects is covered under the
   thermal regulation specification. Pulse testing with a low duty cycle is used.
4. C_{Adj}, when used, is connected between the adjustment pin and ground.
5. Power dissipation within an IC voltage regulator produces a temperature gradient on the die, affecting individual IC components on the die.
   These effects can be minimized by proper integrated circuit design and layout techniques. Thermal Regulation is the effect of these
   temperature gradients on the output voltage and is expressed in percentage of output change per watt of power change in a specified time.
6. Since Long Term Stability cannot be measured on each device before shipment, this specification is an engineering estimate of average
   stability from lot to lot.

APPLICATIONS INFORMATION

Basic Circuit Operation
The LM337 is a 3-terminal floating regulator. In operation, the LM337 develops and maintains a nominal −1.25 V reference (V\text{ref}) between its output and adjustment terminals. This reference voltage is converted to a programming current (I\text{PROG}) by R1 (see Figure 17), and this constant current flows through R2 from ground.

The regulated output voltage is given by:

\[ V_{\text{out}} = V_{\text{ref}} \left( 1 + \frac{R_2}{R_1} \right) + I_{\text{Adj}} R_2 \]

Since the current into the adjustment terminal (I_{\text{Adj}}) represents an error term in the equation, the LM337 was designed to control I_{\text{Adj}} to less than 100 μA and keep it constant. To do this, all quiescent operating current is returned to the output terminal. This imposes the requirement for a minimum load current. If the load current is less than this minimum, the output voltage will rise.

Since the LM337 is a floating regulator, it is only the voltage differential across the circuit which is important to performance, and operation at high voltages with respect to ground is possible.

External Capacitors
A 1.0 μF tantalum input bypass capacitor (C_{\text{in}}) is recommended to reduce the sensitivity to input line impedance.

The adjustment terminal may be bypassed to ground to improve ripple rejection. This capacitor (C_{\text{Adj}}) prevents ripple from being amplified as the output voltage is increased. A 10 μF capacitor should improve ripple rejection about 15 dB at 120 Hz in a 10 V application.

An output capacitance (C_{\text{O}}) in the form of a 1.0 μF tantalum or 10 μF aluminum electrolytic capacitor is required for stability. Using the classical tantalum or aluminum electrolytic capacitor types with non-reduced ESR (Equivalent Series Resistance) value is necessary. Low-ESR or similar capacitor types with reduced ESR value and ceramic capacitors can cause instability or continuous oscillations in the application.

Protection Diodes
When external capacitors are used with any IC regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator.

Figure 18 shows the LM337 with the recommended protection diodes for output voltages in excess of −25 V or high capacitance values (C_{\text{O}} > 25 μF, C_{\text{Adj}} > 10 μF). Diode D1 prevents C_{\text{O}} from discharging thru the IC during an input short circuit. Diode D2 protects against capacitor C_{\text{Adj}} discharging through the IC during an output short circuit. The combination of diodes D1 and D2 prevents C_{\text{Adj}} from the discharging through the IC during an input short circuit.

Load Regulation
The LM337 is capable of providing extremely good load regulation, but a few precautions are needed to obtain maximum performance. For best performance, the programming resistor (R1) should be connected as close to the regulator as possible to minimize line drops which effectively appear in series with the reference, thereby degrading regulation. The ground end of R2 can be returned near the load ground to provide remote ground sensing and improve load regulation.
