

Low Power Offline Constant Current & Constant Voltage Primary Side PWM Current-Mode Controller with/without High Voltage Startup Current Source

NCP1360, NCP1365

The NCP1360/65 offers a new solution targeting output power levels from a few watts up to 20 W in a universal-mains flyback application. Thanks to a novel method this new controller saves the secondary feedback circuitry (opto-coupler and TL431 reference) while achieving excellent line and load regulation.

The NCP1360/65 operates in valley-lockout quasi-resonant peak current mode control mode at nominal load to provide high efficiency. When the secondary-side power starts diminishing, the switching frequency naturally increases until a voltage-controlled oscillator (VCO) takes the lead, synchronizing the MOSFET turn-on in a drain-source voltage valley. The frequency is thus reduced by stepping into successive valleys until the number 4 is reached. Beyond this point, the frequency is linearly decreased in valley-switching mode until a minimum is hit. This technique keeps the output in regulation with the tiniest dummy load. Valley lockout during the first four drain-source valleys prevents erratic discrete jumps and provides good efficiency in lighter load situations.

Features

- Primary-Side Feedback Eliminates Opto-coupler and TL431 Reference
- $\pm 5\%$ Voltage Regulation
- $\pm 10\%$ Current Regulation
- 560 V Startup Current Source
- No Frequency Clamp, 80 or 110 kHz Maximum Switching Frequency Options
- Quasi-Resonant Operation with Valley Switching Operation
- Fixed Peak Current & Deep Frequency Foldback @ Light Load Operation
- External Constant Voltage Feedback Adjustment
- Cycle by Cycle Peak Current Limit
- Build-In Soft-Start
- Over & Under Output Voltage Protection
- Cable Drop Compensation (None, 150 mV, 300 mV or 450 mV Option)
- Wide Operation V_{CC} Range (up to 28 V)

ORDERING INFORMATION

See detailed ordering and shipping information on page 27 of this data sheet.

NOTE: Some of the devices on this data sheet have been **DISCONTINUED**. Please refer to the table on page 27.

- Low Start-up Current (2.5 μ A typ.) with NCP1360
- Clamped Gate-drive Output for MOSFET
- CS & $V_{S/ZCD}$ pin Short and Open Protection
- Internal Temperature Shutdown
- Less than 10 mW No-Load Performance at High Line with NCP1365 Version
- Less than 30 mW No-Load Performance at High Line with NCP1360 Version
- These are Pb-Free Devices

Typical Applications

- Low Power ac-dc Adapters for Chargers.
- Ac-dc USB chargers for Cell Phones, Tablets and Cameras

PIN FUNCTION DESCRIPTION

Pin out NCP1365	Pin out NCP1360	Name	Function
1	6	V_S/ZCD	Connected to the auxiliary winding; this pin senses the voltage output for the primary regulation and detects the core reset event for the Quasi-Resonant mode of operation.
2	5	Comp	This is the error amplifier output. The network connected between this pin and the ground adjusts the regulation loop bandwidth.
3	4	CS	This pin monitors the primary peak current.
4	3	DRV	Controller switch driver.
5	2	GND	Ground reference.
6	1	V_{CC}	This pin is connected to an external auxiliary voltage and supplies the controller.
7	–	NC	Not Connected for creepage distance between high and low Voltage pins
8	–	HV	Connected the high-voltage rail, this pin injects a constant current into the V_{CC} capacitor for starting-up the power supply.

MAXIMUM RATINGS

Symbol	Rating	Value	Unit
$V_{CC(MAX)}$	Maximum Power Supply voltage, VCC pin, continuous voltage	–0.3 to 28	V
$\Delta V_{CC}/\Delta t$	Maximum slew rate on VCC pin during startup phase	+0.4	V/ μ s
$V_{DRV(MAX)}$ $I_{DRV(MAX)}$	Maximum driver pin voltage, DRV pin, continuous voltage Maximum current for DRV pin	–0.3, V_{DRV} (Note 1) –300, +500	V mA
V_{MAX} I_{MAX}	Maximum voltage on low power pins (except pins DRV and VCC) Current range for low power pins (except pins DRV and VCC)	–0.3, 5.5 –2, +5	V mA
V_{HV}	High Voltage pin voltage	–0.3 to 560	V
$R_{\theta J-A}$	Thermal Resistance Junction-to-Air	200	$^{\circ}$ C/W
$T_{J(MAX)}$	Maximum Junction Temperature	150	$^{\circ}$ C
	Operating Temperature Range	–40 to +125	$^{\circ}$ C
	Storage Temperature Range	–60 to +150	$^{\circ}$ C
	Human Body Model ESD Capability per JEDEC JESD22–A114F	2	kV
	Machine Model ESD Capability (All pins except DRV) per JEDEC JESD22–A115C	200	V
	Charged-Device Model ESD Capability per JEDEC JESD22–C101E	500	V

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

- V_{DRV} is the DRV clamp voltage $V_{DRV(high)}$ when V_{CC} is higher than $V_{DRV(high)}$. V_{DRV} is V_{CC} otherwise
- This device contains latch-up protection and exceeds 100 mA per JEDEC Standard JESD78.

APPLICATION INFORMATION

The NCP1365/60 is a flyback power supply controller providing a means to implement primary side constant-voltage and constant-current regulation. This technique does not need a secondary side feedback circuitry, associated bias current and an opto-coupler. NCP1365/60 implements a current-mode architecture operating in quasi-resonant mode. The controller prevents valley-jumping instability and steadily locks out in a selected valley as the power demand goes down. As long as the controller is able to detect a valley, the new cycle or the following drive remains in a valley. Due to a dedicated valley detection circuitry operating at any line and load conditions, the power supply efficiency will always be optimized. In order to prevent any high switching frequency two frequency clamp options are available.

- **Quasi-Resonance Current-mode operation:**

implementing quasi-resonance operation in peak current-mode control optimizes the efficiency by switching in the valley of the MOSFET drain-source voltage. Thanks to a proprietary circuitry, the controller locks-out in a selected valley and remains locked until the input voltage significantly changes. Only the four first valleys could be locked out. When the load current diminishes, valley switching mode of operation is kept but without valley lock-out. Valley-switching operation across the entire input/output conditions brings efficiency improvement and lets the designer build higher-density converters.

- **Frequency Clamp:** As the frequency is not fixed and dependent on the line, load and transformer specifications, it is important to prevent switching frequency runaway for applications requiring maximum switching frequencies up to 90 kHz or 130 kHz. Two frequency clamp options at 80 kHz or 110 kHz are available for this purpose. In case frequency clamp is not needed, a specific version of the 1365/60 exists in which the clamp is deactivated.
- **Primary Side Constant Current Regulation:** Battery charging applications request constant current regulation. NCP1360/65 controls and regulates the output current at a constant level regardless of the input and output voltage conditions. This function offers tight over power protection by estimating and limiting the maximum output current from the primary side, without any particular sensor.
- **Primary Side Constant Voltage Regulation:** By monitoring the auxiliary winding voltage on the primary side, it is possible to determine the end of the transformer demagnetization in order to indirectly measure the output voltage. The end of the auxiliary winding demagnetization corresponds to that of the secondary winding affected by the transformer turns ratio. This auxiliary voltage value captured at this

moment will be used to build the primary-side peak current setpoint in order to control the output voltage.

Figure 43. Constant-Voltage & Constant-Current Mode

- **Soft-Start:** 4 ms internal fixed soft start guarantees a peak current starting from zero to its nominal value with smooth transition in order to prevent any overstress on the power components at each startup.
- **Cycle-by-Cycle peak current limit:** If the max peak current reaches the V_{ILIM} level, the over current protection timer is enabled and starts counting. If the overload lasts T_{OCP} delay, then the fault is latched and the controller stops immediately driving the power MOSFET. The controller enters in a double hiccup mode before autorecovering with a new startup cycle.
- **V_{CC} Over Voltage Protection:** If the V_{CC} voltage reaches the $V_{CC(OVP)}$ threshold the controller enters in latch mode. Thus it stops driving pulse on DRV pin:
 - ♦ **A & C version – (Latched $V_{CC(OVP)}$):** V_{CC} capacitor is internally discharged to the $V_{CC(Clamp)}$ level with a very low power consumption: the controller is completely disabled. Resuming operation is possible by unplugging the line in order to releasing the internal V_{CC} thyristor with a V_{CC} current lower than the $I_{CC(Clamp)}$.
 - ♦ **B version – (Autorecovery):** it enters in double hiccup mode before resuming operation.
- **Winding Short-Circuit Protection:** An additional comparator senses the CS signal and stops the controller if V_{CS} reaches $V_{ILIM}+50\%$ (after a reduced LEB: t_{LEB2}). Short circuit protection is enabled only if 4 consecutive pulses reach SCP level. This small counter prevents any false triggering of short circuit protection during surge test for instance. This fault is latched and operations will be resumed like in a case of V_{CC} Over Voltage Protection.

- **V_{out} Over Voltage Protection:** if the internally–built output voltage becomes higher than V_{OVP} level ($V_{ref_CV1} + 26\%$) a fault is detected.
 - ♦ **A & C version:** This fault is latched and operations are resumed like in the **V_{CC} Over Voltage Protection** case.
 - ♦ **B version:** the part enters in double hiccup mode before resuming operations.
- **V_{out} Under Voltage Protection:** After each circuit power on sequence, V_{out} UVP detection is enabled only after the startup timer T_{EN_UVP} . This timer ensures that the power supply is able to fuel the output capacitor before checking the output voltage in on target. After this startup blanking time, UVP detection is enabled and monitors the Output voltage level. When the power supply is running in constant–current mode and when the output voltage falls below V_{UVP} level, the controller stops sending drive pulses and enters a double hiccup mode before resuming operations (A & B version), or latches off (C version).
- **V_s/ZCD Pin Short Protection:** at the beginning of each off–time period, the V_s/ZCD pin is tested to check whether it is shorted or left open. In case a fault is detected, the controller enters in a double hiccup mode before resuming operations.
- **Temperature Shutdown:** if the junction temperature reaches the T_{SHTDN} level, the controller stop driving the

power mosfet until the junction temperature decreases by $T_{SHTDN(HYS)}$, then the operation is resumed after a double hiccup mode.

Startup Operation

The high–voltage startup current source is connected to the bulk capacitor via the HV pin, it charges the V_{CC} capacitor. During startup phase, it delivers 100 μA to fuel the V_{CC} capacitor. When V_{CC} pin reaches $V_{CC(on)}$ level, the NCP1360/65 is enabled. Before sending the first drive pulse to the power MOSFET, the CS pin has been tested for an open or shorted situation. If CS pin is properly wired, then the controller sends the first drive pulse to the power MOSFET. After sending these first pulses, the controller checks the correct V_s/ZCD pin wiring. Considering the V_s/ZCD pin properly wired, the controller engages a softstart sequence. The softstart sequence controls the max peak current from the minimal frozen primary peak current ($V_{CS(VCO)} = 120$ mV: 15% of V_{LLIM}) to the nominal pulse width by smoothly increasing the level.

Figure 44 illustrates a standard connection of the HV pin to the bulk capacitor. If the controller is in a latched fault mode (ex V_{CC_OVP} has been detected), the power supply will resume the operation after unplugging the converter from the ac line outlet. Due the extremely low controller consumption in latched mode, the release of the latch could be very long. The unplug duration for releasing the latch will be dependent on the bulk capacitor size.

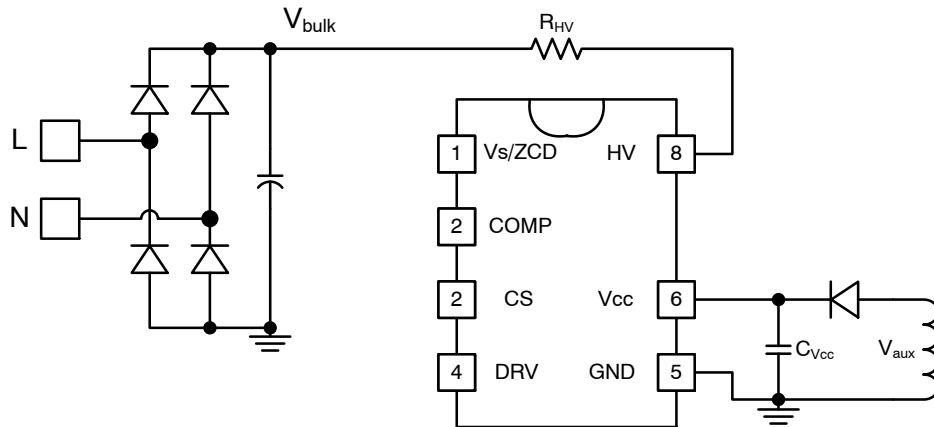

Figure 44. HV Startup Connection to the Bulk Capacitor

The following calculation illustrates the time needed for releasing the latch state:

$$t_{unplug} > \frac{C_{bulk} V_{in_ac} \sqrt{2}}{I_{HV}} \quad (\text{eq. 1})$$

For the following typical application with a 10 μF bulk capacitor and a wide mains input range, in the worst case the power supply needs to be unplug at least for 38 seconds @ 265 V ac and 12 seconds @ 85 Vac. It is important to note that the previous recommendation is no longer valid with the B version, as all the faults are set to autorecovery mode only.

Protecting the Controller Against Negative Spikes

As with any controller built upon a CMOS technology, it is the designer's duty to avoid the presence of negative spikes on sensitive pins. Negative injection has the bad habit to forward–bias the controller substrate and can induce erratic behaviors. Sometimes, the injection can be so strong that internal parasitic SCRs are triggered and latch the controller. The HV pin can be the problem in certain circumstances. During the turn–off sequence, e.g. when the user unplugs the power supply, the controller is still fed by its V_{CC} capacitor and keeps activating the MOSFET ON and

OFF with a peak current limited by R_{sense} . Unfortunately, if the quality factor Q of the resonating network formed by L_p and C_{bulk} is high (e.g. the MOSFET $R_{DS(on)} + R_{sense}$ are small), conditions are met to make the circuit resonate and a negative ringing can potentially appear at the HV pin.

Simple and inexpensive cures exist to prevent the internal parasitic SCR activation. One of them consist of inserting a resistor in series with the HV pin to keep the negative current at the lowest when the bulk swings negative (Figure 44).

Another option (Figure 45) consists of connecting the HV pin directly to the line or neutral input via a high-voltage diode. This configuration offers the benefits to release a latch state immediately after unplugging the power supply from the mains outlet. There is no delay for resetting the controller as there no capacitor keeps the HV bias.

R_{HV} resistor value must be sized as follow in order to guarantee a correct behavior of the HV startup in the worst case conditions:

$$R_{HV} < \frac{V_{in,ac_min} \sqrt{2} - V_{HV(min)_max}}{I_{HV_max}} \quad (\text{eq. 2})$$

Where:

- V_{in,ac_min} is minimal input voltage, for example 85 V ac for universal input mains.
- $V_{HV(min)_max}$ is the worst case of the minimal input voltage needed for the HV startup current source (25 V-max).
- I_{HV_max} is the maximum current delivered by the HV startup current source (150 μ A-max)

With this typical example

$$R_{HV} < \frac{85 \sqrt{2} - 25}{150 \mu} = 633 \text{ k}\Omega,$$

then any value below this one will be ok.

Primary Side Regulation: Constant Current Operation

Figure 46 portrays idealized primary and secondary transformer currents of a flyback converter operating in Discontinuous Conduction Mode (DCM).

Figure 46. Primary and Secondary Transformer Current Waveforms

When the primary power MOSFET is turned on, the primary current is illustrated by the green curve of Figure 46. When the power MOSFET is turned off the primary side current drops to zero and the current into the secondary winding immediately rises to its peak value equal to the primary peak current divided by the primary to secondary turns ratio. This is an ideal situation in which the leakage inductance action is neglected.

The output current delivered to the load is equal to the average value of the secondary winding current, thus we can write:

$$I_{out} = \langle i_{sec}(t) \rangle = \frac{I_{p,pk} t_{demag}}{2N_{ps} t_{sw}} \quad (\text{eq. 3})$$

Where:

- t_{sw} is the switching period
- t_{demag} is the demagnetizing time of the transformer
- N_{ps} is the secondary to primary turns ratio, where N_p and N_s are respectively the transformer primary and secondary turns:

$$N_{ps} = \frac{N_s}{N_p} \quad (\text{eq. 4})$$

- $I_{p,pk}$ is the magnetizing peak current sensed across the sense resistor on CS pin:

$$I_{p,pk} = \frac{V_{CS}}{R_{sense}} \quad (\text{eq. 5})$$

Internal constant current regulation block is building the constant current feedback information as follow:

$$V_{FB_CC} = V_{ref_CC} \frac{t_{sw}}{t_{demag}} \quad (\text{eq. 6})$$

As the controller monitors the primary peak current via the sense resistor and due to the internal current setpoint divider (K_{comp}) between the CS pin and the internal feedback information, the output current could be written as follow:

$$I_{out} = \frac{V_{ref_CC}}{8N_{ps}R_{sense}} \quad (\text{eq. 7})$$

The output current value is set by choosing the sense resistor value:

$$R_{sense} = \frac{V_{ref_CC}}{8N_{ps}I_{out}} \quad (\text{eq. 8})$$

Primary Side Regulation: Constant Voltage Operation

In primary side constant voltage regulation, the output voltage is sensed via the auxiliary winding. During the on-time period, the energy is stored in the transformer gap. During the off-time this energy stored in the transformer is delivered to the secondary and auxiliary windings.

As illustrated by Figure 47, when the transformer energy is delivered to the secondary, the auxiliary voltage sums the output voltage scaled by the auxiliary and secondary turns ratios and the secondary forward diode voltage. This secondary forward diode voltage could be split in two elements: the first part is the forward voltage of the diode (V_f), and the second is related to the dynamic resistance of the diode multiplied by secondary current ($R_d \cdot I_s(t)$). Where this second term will be dependant of the load and line conditions.

Figure 47. Typical Idealized Waveforms of a Flyback Transformer in DCM

To reach an accurate primary-side constant-voltage regulation, the controller detects the end of the demagnetization time and precisely samples output voltage level seen on the auxiliary winding. As this moment coincides with the secondary-side current equal to zero, the diode forward voltage drop becomes independent from the loading conditions.

Thus when the secondary current $I_s(t)$ reaches zero ampere, the auxiliary is sensed:

$$V_{aux} = V_{out} \frac{N_{pa}}{N_{ps}} \quad (\text{eq. 9})$$

Where: N_{pa} is the auxiliary to primary turns ratio, where N_p & N_a are respectively the primary and auxiliary turns:

$$N_{pa} = \frac{N_a}{N_p} \quad (\text{eq. 10})$$

Figure 49 illustrates how the constant voltage feedback has been built. The auxiliary winding voltage must be scaled down via the resistor divider to V_{ref_CV1} level before building the constant voltage feedback error.

$$V_{ref_CV1} = \frac{R_{s2}}{R_{s1} + R_{s2}} V_{aux} \quad (\text{eq. 11})$$

By inserting Equation 9 into Equation 11 we obtain the following equation:

$$V_{ref_CV1} = \frac{R_{s2}}{R_{s1} + R_{s2}} \frac{N_{pa}}{N_{ps}} V_{out} \quad (\text{eq. 12})$$

Please note that the controller regulates the output voltage through the ZCD voltage when the voltage value in a knee is 2.7 V (see the Figure 48). Therefore, the value 2.7 V should be used as V_{ref_CV1} parameter instead of 2.5 V stated in the Electrical Characteristics table. Also, all voltage drops between secondary winding and measured output voltage needs to be considered and add to the output voltage value. It's recommended to verify the actual output voltage value in the real application and tune up the ZCD divider.

$$V_{OUT} = 2.7 \text{ V} \times \frac{N_{ps}}{N_{pa}} \times \frac{R_{s1} + R_{s2}}{R_{s2}} - V_{f(0)} \quad (\text{eq. 13})$$

Figure 48. ZCD Voltage Waveform during Constant Voltage Regulation

Once the sampled V_{out} is applied to the negative input terminal of the operational transconductance amplifier (OTA) and compared to the internal voltage reference an adequate voltage feedback is built. The OTA output being pinned out, it is possible to compensate the converter and adjust step load response to what the project requires.

The OTA output being pinned out, it is possible to compensate the converter and adjust step load response to what the project requires.

Figure 49. Constant Voltage Feedback Arrangement

When the power MOSFET is released at the end of the on time, because of the transformer leakage inductance and the drain lumped capacitance some voltage ringing appears on the drain node. These voltage ringings are also visible on the auxiliary winding and could cheat the controller detection circuits. To avoid false detection operations, two protecting circuits have been implemented on the V_S/ZCD pin (see Figure 50):

1. An internal switch grounds the V_S/ZCD pin during $t_{on} + t_{short_ZCD}$ in order to protect the pin from negative voltage.
2. In order to prevent any misdetection from the zero crossing block an internal switch disconnects V_S/ZCD pin until t_{blank_ZCD} time (1.5 μs typ.) ends.

Figure 50. V_S/ZCD Pin Waveforms

Constant-Current and Constant-Voltage Overall Regulation:

As already presented in the two previous paragraphs, the controller integrates two different feedback loops: the first one deals with the constant-current regulation scheme while the second one builds the constant-voltage regulation. One of the two feedback paths sets the primary peak current into the transformer. During startup phase, however, the peak current is controlled by the soft-start.

Zero Current Detection

The NCP1365 integrates a quasi-resonant (QR) flyback controller. The power switch turn-off of a QR converter is determined by the peak current whose value depends on the feedback loop. The switch restart event is determined by the transformer demagnetization end. The demagnetization end

is detected by monitoring the transformer auxiliary winding voltage. Turning on the power switch once the transformer is demagnetized (or reset) reduces turn-on switching losses. Once the transformer is demagnetized, the drain voltage starts ringing at a frequency determined by the transformer magnetizing inductance and the drain lumped capacitance, eventually settling at the input voltage value. A QR controller takes advantage of the drain voltage ringing and turns on the power switch at the drain voltage minimum or “valley” to reduce turn-on switching losses and electromagnetic interference (EMI).

As sketched by Figure 51, a valley is detected once the ZCD pin voltage falls below the QR flyback demagnetization threshold, $V_{ZCD(TH)}$, typically 45 mV. The controller will switch once the valley is detected or increment the valley counter depending on FB voltage.

Figure 51. Valley Lockout Detection Circuitry internal Schematic

Timeout

The *ZCD* block actually detects falling edges of the auxiliary winding voltage applied to the *ZCD* pin. At start-up or during other transient phases, the *ZCD* comparator may be unable to detect such an event. Also, in the case of extremely damped oscillations, the system may not succeed in detecting all the valleys required by valley lockout operation (VLO, see next section). In this condition, the NCP1365 ensures continued operation by incorporating a maximum timeout period that resets itself when a demagnetization phase is properly detected. In case the ringing signal is too weak or heavily damped, the timeout signal supersedes the *ZCD* signal for the valley counter. Figure 51 shows the timeout period generator circuit schematic. The timeout duration, t_{out} , is set to 5.5 μs (typ.).

During startup, the output voltage is still low, leading to long demagnetization phase, difficult to detect since the auxiliary winding voltage is small as well. In this condition, the t_{out} timeout is generally shorter than the inductor demagnetization period and if used to restart a switching cycle, it can cause continuous current mode (CCM) operation for a few cycles until the voltage on the *ZCD* pin is high enough for proper valleys detection. A longer timeout period, t_{outSS} , (typically 44 μs) is therefore set during soft-start to prevent CCM operation.

In VLO operation, the timeout occurrences are counted instead of valleys when the drain-source voltage oscillations are too damped to be detected. For instance, assume the circuit must turn on at the third valley and the *ZCD* ringing only enables the detection of:

- Valleys #1 to #2: the circuit generates a *DRV* pulse t_{out} (steady-state timeout delay) after valley #2 detection.

- Valley #1: the timeout delay must run twice so that the circuit generates a *DRV* pulse 10 μs ($2 \cdot t_{out}$ typ.) after valley #1 detection.

Valley LockOut (VLO) and Frequency Foldback (FF)

The operating frequency of a traditional Quasi-Resonant (QR) flyback controller is inversely proportional to the system load. In other words, a load reduction increases the operating frequency. A maximum frequency clamp can be useful to limit the operating frequency range. However, when associated with a valley-switching circuit, instabilities can arise because of the discrete frequency jumps. The controller tends to hesitate between two valleys and audible noise can be generated.

To avoid this issue, the NCP1360/65 incorporates a proprietary valley lockout circuitry which prevents so-called valley jumping. Once a valley is selected, the controller stays locked in this valley until the input level or output power changes significantly. This technique extends QR operation over a wider output power range while maintaining good efficiency and naturally limiting the maximum operating frequency.

The operating valley (from 1st to 4th valley) is determined by the internal feedback level (*FB* node on Figure 4). As *FB* voltage level decreases or increases, the valley comparators toggle one after another to select the proper valley.

The decimal counter increases each time a valley is detected. The activation of an “n” valley comparator blanks the “n-1” or “n+1” valley comparator output depending if V_{FB} decreases or increases, respectively. Figure 52 shows a typical frequency characteristic obtained at low line in a 10 W charger.

Figure 52. Typical Switching Frequency versus Output Power Relationship in a 10 W Adapter

When an “n” valley is asserted by the valley selection circuitry, the controller locks in this valley until the *FB* voltage decreases to the lower threshold (“n+1” valley activates) or increases to the “n valley threshold” + 600 mV (“n-1” valley activates). The regulation loop adjusts the

peak current to deliver the necessary output power at the valley operating point. Each valley selection comparator features a 600 mV hysteresis that helps stabilize operation despite the *FB* voltage swing produced by the regulation loop.

Table 1. VALLEY FB THRESHOLD ON CONSTANT VOLTAGE REGULATION

FB Falling		FB Rising	
1 st to 2 nd valley	2.5 V	FF mode to 4 th	2.5 V
2 nd to 3 rd valley	2.3 V	4 th to 3 rd valley	2.7 V
3 rd to 4 th valley	2.1 V	3 rd to 2 nd valley	2.9 V
4 th to FF mode	1.9 V	2 nd to 1 st valley	3.1 V

Frequency Foldback (FF)

As the output current decreases (*FB* voltage decreases), the valleys are incremented from 1 to 4. In case the fourth valley is reached, the *FB* voltage further decreases below 1.9 V and the controller enters the frequency foldback mode (FF). The current setpoint being internally forced to remain above 0.12 V (setpoint corresponding to $V_{Comp} = 1.9$ V), the controller regulates the power delivery by modulating the switching frequency. When an output current increase causes *FB* to exceed the 2.5 V FF upper threshold (600-mV hysteresis), the circuit recovers *VLO* operation.

In frequency foldback mode, the system reduces the switching frequency by adding some dead-time after the 4th valley is detected. However, in order to keep the high

efficiency benefit inherent to the QR operation, the controller turns on again with the next valley after the dead time has ended. As a result, the controller will still run in valley switching mode even when the FF is enabled. This dead-time increases when the *FB* voltage decays. There is no discontinuity when the system transitions from *VLO* to FF and the frequency smoothly reduces as *FB* goes below 1.9 V.

The dead-time is selected to generate a 2 μ s dead-time when V_{Comp} is decreasing and crossing V_{HVCOD} (1.9 V typ.). At this moment, it can linearly go down to the minimal frequency limit ($f_{VCO(min)} = 200, 600$ or 1200 Hz version are available). The generated dead-time is 1 μ s when V_{Comp} is increasing and crossing V_{HVCOI} (2.5 V typ.).

Figure 53. Valley Lockout Threshold

Current Setpoint

As explained in this operating description, the current setpoint is affected by several functions. Figure 54 summarizes these interactions. As shown by this figure, the current setpoint is the output of the control law divided by K_{comp} (4 typ.). This current setpoint is clamped by the soft-start slope as long as the peak current requested by the FB_CV or FB_CC level are higher. The softstart clamp is starting from the frozen peak current ($V_{CS(VCO)} = 120$ mV typ.) to V_{ILIM} (0.8 V typ.) within 4 ms (t_{ss}).

However, this internal FB value is also limited by the following functions:

- A minimum setpoint is forced that equals $V_{CS(VCO)}$ (0.12 V, typ.)
- In addition, a second OCP comparator ensures that in any case the current setpoint is limited to V_{ILIM} . This ensures the MOSFET current setpoint remains limited to V_{ILIM} in a fault condition.

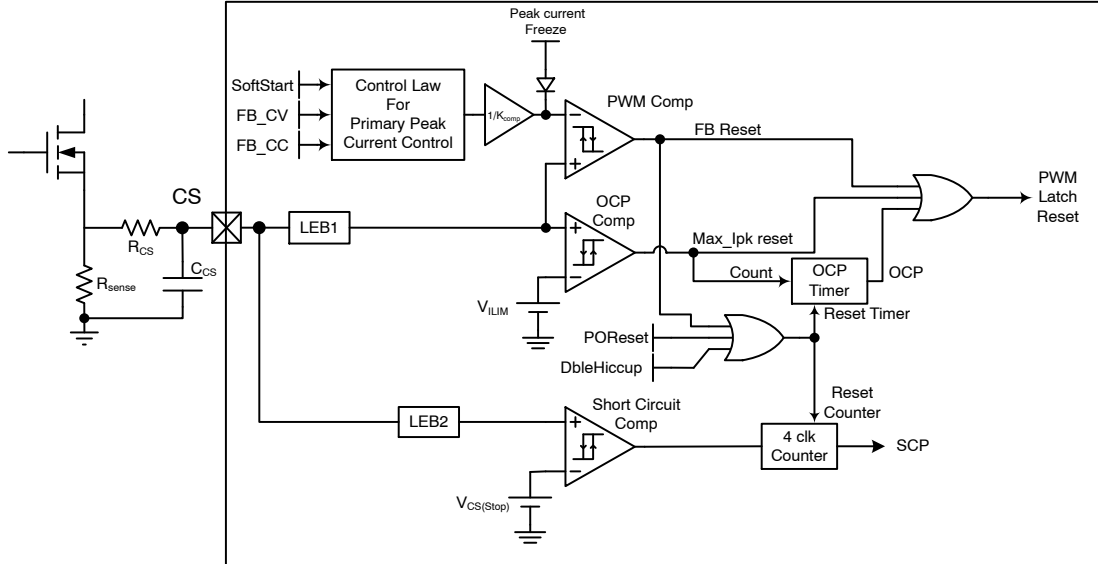

Figure 54. Current Setpoint

A 2nd Over-Current Comparator for Abnormal Overcurrent Fault Detection

A severe fault like a winding short-circuit can cause the switch current to increase very rapidly during the on-time. The current sense signal significantly exceeds V_{ILIM} . But, because the current sense signal is blanked by the LEB circuit during the switch turn on, the power switch current can abnormally increase, possibly causing system damages.

The NCP1360/65 protects against this dangerous mode by adding an additional comparator for abnormal overcurrent fault detection or short-circuit condition. The current sense signal is blanked with a shorter LEB duration, t_{LEB2} , typically 120 ns, before applying it to the short-circuit comparator. The voltage threshold of this extra comparator, $V_{CS(stop)}$, is typically 1.2 V, set 50% higher than V_{ILIM} . This

is to avoid interference with normal operation. Four consecutive abnormal overcurrent faults cause the controller to enter in auto-recovery mode. The count to 4 provides noise immunity during surge testing. The counter is reset each time a *DRV* pulse occurs without activating the fault overcurrent comparator or after double hiccup sequence or if the power supply is unplugged with a new startup sequence after the initial power on reset.

Standby Power Optimization

Assuming the no-load standby power is a critical parameter, the NCP1360/65 is optimized to reach an ultra low standby power. When the controller enters standby mode, a part of the internal circuitry has been disabled in

order to minimize its supply current. When the STBY mode is enabled, the consumption is only 200 μA (I_{CC4}) with the 200 Hz minimal frequency option.

Cable Drop Compensation

NCP1360/65 integrates an internal cable drop compensation. This circuitry compensates the drop due to the cable connected between the PCB output of the charger and the final equipment. As the drop is linearly varying with the output current level, this level can be compensated by accounting for the load output current.

Figure 55 illustrates the practical implementation of the cable compensation with the NCP1360/65 controller.

Figure 55. Cable Compensation Implementation

The end of output cable voltage level could be written as follows:

$$V_{\text{out_cable_end}}(t) = V_{\text{out_connector}}(t) - R_{\text{cable}} I_{\text{out}}(t) \quad (\text{eq. 14})$$

$$V_{\text{out_cable_end}}(t) = V_{\text{out}} + V_{\text{CBC}}(t) \quad (\text{eq. 15})$$

V_{out} corresponds to the nominal output level at no-load. It is independent of the output current level.

Then the cable compensation level could be determined as follow:

$$V_{\text{CBC}}(t) = \text{CBC} \frac{I_{\text{out}}(t)}{I_{\text{out_nom}}} \quad (\text{eq. 16})$$

Where:

- ♦ CBC corresponds to the cable compensation option selected (No comp, 150, 300 or 450 mV)
- ♦ $I_{\text{out}}(t)$ corresponds to the output current currently sunk by the load estimated on by the controller on the primary side.
- ♦ $I_{\text{out_nom}}$ the nominal output current level of the power supply.

Fault mode and Protection

- ♦ CS pin: at each startup, a 55 μA (I_{CS}) current source pulls up the CS pin to disable the controller if the pin is left open or grounded. Then the controller enters in a double hiccup mode.

- ♦ $V_{\text{S/ZCD}}$ pin: after sending the first drive pulse the controller checks the correct wiring of $V_{\text{S/ZCD}}$ pin: after the ZCD blanking time, if there is an open or short conditions, the controller enters in double hiccup mode.

Thermal Shutdown: An internal thermal shutdown circuit monitors the junction temperature of the IC. The controller is disabled if the junction temperature exceeds the thermal shutdown threshold (T_{SHDN}), typically 150°C. A continuous V_{CC} hiccup is initiated after a thermal shutdown fault is detected. The controller restarts at the next $V_{\text{CC(on)}}$ once the IC temperature drops below T_{SHDN} reduced by the thermal shutdown hysteresis ($T_{\text{SHDN(HYS)}}$), typically 40°C. The thermal shutdown is also cleared if V_{CC} drops below $V_{\text{CC(reset)}}$. A new power up sequences commences at the next $V_{\text{CC(on)}}$ once all the faults are removed.

Driver

The NCP1365 maximum supply voltage, $V_{\text{CC(max)}}$, is 28 V. Typical high-voltage MOSFETs have a maximum gate voltage rating of 20 V. The DRV pin incorporates an active voltage clamp which limits the gate voltage on the external mosfet. The DRV voltage clamp, $V_{\text{DRV(high)}}$ is set to 13 V maximum.
