AND9200/D

4 Key Steps to Design a NCL30088-Controlled LED Driver

Description
This paper proposes the key steps to rapidly design a NCL30088-driven flyback converter to power an LED string. The process is illustrated by a practical 10 W, universal mains application:

- Maximum Output Power: 10 W
- Input Voltage Range: 90 to 265 V rms
- Output Voltage Range: 12 to 20 V dc
- Output Current: 500 mA

Introduction
The NCL30088 is a driver for power-factor corrected flyback, non-isolated buck-boost and SEPIC converters. The current-mode, quasi-resonant architecture optimizes the efficiency by turning on the MOSFET when the drain-source voltage is minimal (valley). At high line, the circuit delays the MOSFET turn on until the second valley is detected to reduce the switching losses. An internal proprietary circuitry controls the input current in such a way that a power factor as high as 0.99 and an output current deviation below ±2% are typically obtained without the need for a secondary-side feedback. The circuit further contains a suite of powerful protections to ensure a robust LED driver design without the need for extra components or overdesign. Among them, one can list:

- Over Temperature Thermal Fold-back: connecting a NTC to the SD pin allows for gradual reduction of the LED current down to 50% of its nominal value when the temperature is excessive. If the current reduction does not prevent the temperature from reaching a second level, the controller stops operating (SD_OTP).
- Over Voltage Protection (SD_OVP): A Zener diode can further be used on the SD pin to provide an adjustable OVP protection (SD OVP).
- Cycle-by-cycle Peak Current Limit: when the current sense voltage exceeds the internal threshold (\( V_{ILIM} \)), the MOSFET immediately turns off (cycle-by-cycle current limitation).
- Winding and Output Diode Short-circuit Protection (WODSCP): an additional comparator stops the controller if the CS pin voltage exceeds (150% \( V_{ILIM} \)) for 4 consecutive cycles. This feature can protect the converter if a winding or the output diode is shorted or simply if the transformer saturates.

- Output Short-circuit Protection (AUXSCP): If the ZCD pin voltage remains low for a 90-ms time interval, the controller stops pulsating until 4 seconds has elapsed.
- Open LED Protection: if the \( V_{CC} \) pin voltage exceeds the OVP threshold, the controller shuts down and waits 4 seconds before restarting switching operation.
- Floating/Short Pin Detection: the circuit can detect most of these situations which helps pass safety tests.

Selecting the Right NCL30088 Version
There exist four NCL30088 versions. They differ in:

- Their respective protection mode. The WODSCP, AUXSCP and the SD over-temperature (OTP) and over-voltage (OVP) protections are latching-off (A and C versions) or auto-recovery (the circuit resumes operation after a 4-second delay – B and D versions).
- The internal duty-ratio limitation. NCL30088A/B duty-ratio is internally limited to 50% at the top of the lowest line sinusoid. They are recommended if the lowest line peak voltage is higher than the inductor demagnetization voltage, i.e.,:
  - If \( \frac{1}{2} \cdot (V_{in, rms})_{LL} \geq V_{out} + V_f \) with non-isolated converters,
  - If \( \frac{1}{2} \cdot (V_{in, rms})_{LL} \geq \frac{n_p}{n_s} (V_{out} + V_f) \) in flyback applications

where \( (V_{in, rms})_{LL} \) is the lowest-line rms voltage (85 or 90 V rms in general) and \( (V_f) \) is the output diode forward voltage. The C and D versions that allow the duty-ratio to reach 60% at the top of the lowest line sinusoid, must be preferred otherwise. See Table 1.
Table 1: SELECTING THE RIGHT NCL30088 VERSION

</tr>
</tbody>
</table>

1. $(V_{in,rms})_{LL}$ is the lowest-line rms voltage (e.g., 85 V rms), $(V_f)$, the output diode forward voltage.
2. $(V_{in,rms})_{LL}$ is the lowest-line rms voltage (e.g., 85 V rms), $(V_f)$, the output diode forward voltage.
3. Please contact local sales representative for availability.

As an example, let’s assume that we must design a 90 to 265 V rms, non-isolated buck-boost converter whose output can be as high as 150 V. Let’s see if A/B version can be used.

$$\sqrt{2} (V_{in,rms})_{LL} = \sqrt{2} \cdot 90 \approx 127V \leq V_{out} + V_f \approx 150V$$ (eq. 1)

Eq. 1 indicates that the Table 1 condition of using the A and B versions in non-isolated converters applications is met. Hence, the A/B version is not recommended while the C or D version is ok since:

$$\frac{3}{2} \cdot \sqrt{2} (V_{in,rms})_{LL} = \frac{3}{2} \cdot \sqrt{2} \cdot 90 \approx 191V \geq V_{out} + V_f \approx 150V$$ (eq. 2)

Generally speaking, the A and B versions are typically preferred in narrow-mains non-isolated converters or flyback LED drivers [the turns ratio of isolated flyback converters, gives some flexibility – see Table 1 conditions]. C and D versions are generally to be selected for wide-mains, non-isolated converters.

If the duty-ratio limitation is exceeded by your application, the LED current will be below its nominal value at the lowest line voltage but will meet the target when the input voltage level is sufficient. Thus, you can start with the NCL30088A or the NCL30088B and consider the NCL30088C or NCL30088D if the LED current is too low at the lowest line levels. By the way, a symptom of the duty-ratio limitation effect can be observed as shown by Figure 1 where the input current is clamped by the over-current protection during normal load conditions.

Figure 1. Current Over-current Limitation

$$(V_{ILIM} \text{ is the Over-current Threshold, } R_{sense} \text{ the Current Sense Resistor})$$

Our application of interest is a flyback converter. In this case, the turns ratio must be considered when selecting the appropriate version. We will see that in this specific case, the NCL30088B is the appropriate option.
LED Driver Dimensioning

**Figure 2. Basic Schematic**

**STEP 1: POWER COMPONENTS SELECTION**

Basically, the transformer, the output capacitor and the power silicon devices are dimensioned “as usual”, that is, as done with any other PF corrected, quasi-resonant flyback converter. This chapter does not detail this process, but highlights the major points.

**Transformer Selection**

*Selecting the Auxiliary Winding Number of Turns*

An auxiliary winding is necessary for zero current detection and to provide the $V_{CC}$ voltage. The output voltage of a LED driver generally exhibits a large range. The $V_{CC}$ voltage provided by the auxiliary winding will vary in a similar manner. The NCL30088 features a large $V_{CC}$ range to address these variations. Practically, after start-up, the operating range is 9.4 V up to 25.5 V.

NOTE: $(V_{CC(OVP)})_{min} = 25.5$ V is the threshold minimum value of the $V_{CC}$ over-voltage protection. This safety feature protects the circuit if the LED string happens to be disconnected.

The auxiliary winding number of turns can be selected so that the auxiliary voltage is slightly below $(V_{CC(OVP)})_{min}$ when the output voltage is at a maximum factoring in impact of the 100/120-Hz ripple. Practically, after start-up, the operating range is 9.4 V up to 25.5 V.

$$n_{AUX} \leq n_S \cdot \frac{25.5}{20 + 1} \approx 1.3 \cdot n_S \quad \text{(eq. 5)}$$

Practically, we will select $(n_{AUX} = n_S)$.

In this case, $V_{CC}$ will be in the range of $V_{out}$, with some deviations due to the imperfect coupling.

Selecting the Secondary Winding Number of Turns

In general, $N_{PS}$, the secondary to primary transformer turns ratio $(N_{PS} = n_S / n_P)\ [n_p$ designates the primary number of turns, $n_S$, the secondary number of turns] is selected as low as possible so that the input current stress is reduced. $N_{PS}$ cannot be too small however. $N_{PS}$ sets the amount of voltage reflected during the off-time (see Figure 3) and hence, must be high enough to limit the voltage stress across the primary-side MOSFET. Indeed, the voltage to be sustained by the primary-side MOSFET and the output diode are:

$$V_{DS,\max} = \sqrt{2} (V_{in,rms})_{\max} + \frac{V_{out} + V_i}{N_{PS}} + V_{Q-ov}$$

$$V_{diode,\max} = N_{PS} \sqrt{2} (V_{in,rms})_{\max} + V_{out} + V_i + V_{D-ov} \quad \text{(eq. 6)}$$

Where:

- $N_{PS}$ is the secondary to primary transformer turns ratio $N_{PS} = n_S / n_P$
- $V_{Q-ov}$ is the MOSFET overvoltage shown in Figure 3. This overshoot is due to the leakage inductor reset. It is limited by the clamping network consisting of $D_C$, $C_C$ and $R_C$ of Figure 2.
- $V_{D-ov}$ is a similar overshoot that occurs across the output diode when the MOSFET turns on.
The clamping network is often designed so that $V_{Q-ov}$ is between 50% and 100% of the reflected voltage:

$$V_{Q-ov} = k_c \cdot \frac{V_{out} + V_f}{N_{PS}} \text{ with } 0.5 \leq k_c \leq 1.0 \quad (eq. 7)$$

We can estimate the maximum voltage reached on the drain node, considering $V_{out(OVP)}$ level as the maximum output voltage:

$$V_{ds,max} = \sqrt{2} \cdot (V_{in, rms})_{HL} + \frac{(1 + k_c)(V_{out(OVP)} + V_f)}{N_{PS}} \leq 85\%V_{DSS} \quad (eq. 8)$$

Some derating is generally requested. The typically-applied 15% safety factor implies that the MOSFET voltage does not exceed 85% of its breakdown voltage. Hence:

$$\frac{n_p}{n_s} \leq \frac{85\%V_{DSS} - \sqrt{2} \cdot (V_{in, rms})_{HL}}{(1 + k_c)(V_{out(OVP)} + V_f)} \quad (eq. 9)$$

Where $V_{DSS}$ is the MOSFET breakdown voltage.

Finally:

$$f_{sw} = \frac{(V_{in, rms})^2}{2L_{PP, in, avg}} \cdot \left( \frac{V_{out} + V_f}{N_{PS} v_{in}(t) + V_{out} + V_f} \right)^2 \quad (eq. 13)$$

The switching frequency is a rising function of the rms line voltage. At a given line magnitude, the switching frequency is yet higher near the line zero crossing and decays as the line voltage rises due to the $(v_{in}(t))$ term.

Note that when high-line conditions are detected (see NOTE), the NCL30088 does not operate in quasi-resonant mode but delays the MOSFET turn on until the 2nd valley is detected (see Figure 4). This reduces the switching frequency upper range and optimizes the high-line efficiency.

NOTE: The input voltage is sensed by the $V_S$ pin for brown-out protection, feedforward and line range detection. High-line conditions are detected when the $V_S$ pin voltage exceeds 2.4 V typically. See data sheet for more details.
The primary inductor will be selected with respect to the targeted switching frequency range, keeping in mind that:

- High switching frequency levels reduce the size of the storage elements
- Conversely, increasing the switching frequency leads to more switching noise and losses. Also, EMI filtering may be tougher because of the EMI generated at the switching frequency and close harmonic levels. Most power supplies have to meet standards which apply to frequencies above 150 kHz. That is why SMPS designers often select $F_{SW} = 130 \text{ kHz}$ to keep the fundamental component below 150 kHz and then out of the regulation scope. Often, 65 kHz is also chosen to not have to damp harmonic 2 too.

As the rule of thumb, let us select $L_P$ as follows:

- In wide mains application: choose $L_P$ so that the switching frequency is below 65 kHz at the low-line range nominal voltage (typically 115 V rms) over a large part of the sinusoid. Practically, we can select that the frequency target will have to meet starting from $(V_{in,pk})^{2}$ that is $(\sqrt{2} \cdot 115/2)$. This arbitrary choice relies on the idea that for below this line voltage level the input current is relatively small and easy to filter. Check that at the high-line nominal voltage (230 V rms typically), the switching frequency stays below 65 kHz thanks to the valley-2 operation.
- Similarly, in a narrow mains operation case, select $L_P$ so that the switching frequency is below 65 kHz at the nominal line voltage when $(V_a(t) = V_{in,pk}/2)$

Our application is a wide-range one.

Let us compute $L_P$ so that at 115 V rms, the switching frequency is below $f_{sw,T} = 65 \text{ kHz}$:

$$L_P \geq \frac{(V_{in,rms})}{2 f_{sw,T} P_{in,avg}} \left( \frac{V_{out} + V_f}{N_{PS} \left( \frac{V_{in,rms}}{2} + V_{out} + V_f \right)} \right)^2 \quad \text{(eq. 14)}$$

Which leads to:

$$L_P \geq \frac{115^2}{2 \cdot 65 \cdot 10^3 \cdot 12 \left( \frac{12 + 1}{6 - \frac{115}{2} + 12 + 1} \right)^2} \approx 2 \text{ mH} \quad \text{(eq. 15)}$$

Finally we have to consider the primary current magnitude constraints:

$$I_{L,pk}^{\max} = 2 \sqrt{2} \cdot \frac{P_{in,avg}^{\max}}{(V_{in,rms})_{LL}} \cdot \left( 1 + \frac{N_{PS} (V_{in,rms})_{LL}}{V_{out} + V_f} \right) \quad \text{(eq. 16)}$$

$$I_{L_{rms}}^{\max} = 2 \sqrt{3} \cdot \frac{P_{in,avg}^{\max}}{(V_{in,rms})_{LL}} \sqrt{1 + \frac{16 \sqrt{2} \cdot (V_{in,rms})_{LL}^2}{3 \pi \cdot \frac{V_{out} + V_f}{N_{PS}} + 6 \pi \cdot (V_{in,rms})_{LL}^2}} \quad \text{(eq. 17)}$$

In our application, assuming an efficiency of 84% ($(P_{in,avg}^{\max} = 12 \text{ W}$), Eq. 16 and Eq. 17 lead to:

$$I_{L,pk}^{\max} = 2 \sqrt{2} \cdot \frac{12}{90} \cdot \left( 1 + \frac{90}{20 + 1} \right) \approx 0.65 \text{ A} \quad \text{(eq. 18)}$$

$$I_{L_{rms}}^{\max} = 2 \sqrt{3} \cdot \frac{12}{90} \sqrt{1 + \frac{16 \sqrt{2} \cdot 90}{3 \pi \cdot 6 \cdot 21} + \frac{6 \pi \cdot 90^2}{4 \left( 6 \cdot 21 \right)^2}} \approx 350 \text{ mA} \quad \text{(eq. 19)}$$

We selected transformer 750871144 from Wurth Elektronik with the following characteristics: $L_P = 1.9 \text{ mH}$, $n_P / n_{AUX} = n_P / n_S = 6$. 

---

**Figure 4. Quasi-Resonant Mode in Low Line (Left), Turn On at Valley 2 when in High Line (Right)**
Power Switches

**MOSFET**

The voltage constraints on the MOSFET have been discussed in the transformer section. Conduction losses depend on the MOSFET rms current which can be computed with the following equation:

\[
(i_{Q,\text{rms}})_{\text{max}} = \frac{2}{3} \left( \frac{P_{\text{in,avg}}}{(V_{\text{in,rms}})_{\text{LL}}} \right) \sqrt{1 + \frac{8\sqrt{3}}{3\pi} \left( \frac{V_{\text{out}} + V_f}{V_{\text{in,rms}}}_{\text{LL}} \right)^2} \]  

(eq. 20)

A NDD03N80 MOSFET is selected (DPAK, 800 V, 4.5 Ω).

**Output Diode**

Similarly, the voltage constraints have been discussed in the previous section.

Losses are mainly produced by the average current flowing through the diode. This average is simply the LED current (0.5 A in our case).

A 200-V, 2-A SMB diode is selected (MURS220).

**Snubber and Clamping Network**

A snubber capacitor can be placed across the MOSFET to reduce the dV/dt and lower the switching noise. A 47-pF, 1,000-V capacitor is placed in our application (C\text{2} of Figure 9). Note that for optimal operation, it is recommended to connect the snuber capacitor between the MOSFET drain and source terminals rather than between drain and ground.

When the MOSFET turns off, the magnetizing inductor energy is conveyed to the secondary side and charges the output. The leakage inductor current cannot be used by the output. It must be diverted from the MOSFET. If not, the leakage inductor energy defined in Eq. 22. From this, we can reduce the dV/dt and lower the switching noise. A 47-pF, 4.5 Ω capacitor, the CC negative terminal should preferably be connected to the MOSFET source rather than to ground.

The energy due to the leakage inductor must be handled. It is maximal when the primary current exceeds its limit where V\text{ILIM} is the over-current protection threshold and R\text{sense}, the current sense resistor:

\[
E_{L_{\text{leak}}} = \frac{1}{2} L_{\text{leak}} \left( \frac{V_{\text{ILIM}}}{R_{\text{sense}}} \right)^2 \cdot \frac{(1 + k_C)(V_{\text{out(OVP)}} + V_f)}{N_{PS}} \cdot \left( \frac{V_{\text{out(OVP)}} + V_f}{N_{PS}} \right) \cdot (V_{\text{in,ms}})_{\text{HL}} \cdot f_{SW} \]  

(eq. 21)

This energy of Eq. 21 must be equal or higher than the leakage inductor energy defined in Eq. 22. From this, we can deduce the following minimum R\text{C} value:

\[
R_C \leq \frac{1}{2} k_C \cdot L_{\text{leak}} \left( \frac{V_{\text{ILIM}}}{R_{\text{sense}}} \right)^2 \cdot \frac{(1 + k_C)(V_{\text{out(OVP)}} + V_f)}{N_{PS}} \cdot \left( \frac{V_{\text{out(OVP)}} + V_f}{N_{PS}} \right) + \frac{1}{2} k_C \cdot \left( \frac{V_{\text{in,ms}}}_{\text{HL}} \right)^2 \cdot f_{SW} \]  

(eq. 23)
Select the $C_C$ capacitor so that the time constant $(R_C \cdot C_C)$ is large compared to a switching period, practically, in the range of 1 ms.

Since in our application, we have selected ($k_C = 80\%$), it comes:

$$R_C \leq \frac{28 \cdot 6 \left(180\% \cdot 28 \cdot 6 + \sqrt{2} \cdot 265\right)}{\frac{1}{2 \cdot 60\%} 20 \mu \left(\frac{1}{28}\right)^2} \approx 315 \, \text{k\Omega} \quad \text{(eq. 24)}$$

This resistor will dissipate $\frac{\left(180\% \cdot 28 \cdot 6\right)^2}{315 \, \text{k\Omega}} \approx 290 \, \text{mW}$

Two 470 k\Omega, 1/2 W resistors are placed in parallel for the following effective resistance: (470 k || 470 k = 235 k\Omega).

A 4.7 nF/100 V capacitor is implemented for $C_C$ that with $R_C$ forms a 1.1 ms time constant.

**Output Capacitor**

The power delivered by PFC converters exhibits a large ac component at twice the line frequency. To some extend, the output capacitor compensates for it but yet, the output current exhibits some ripple inversely proportional to the capacitor value ($C_{out}$).

Below equation expresses the current ripple:

$$\frac{(\Delta I_{out,pk-pk})_{out,nom}}{I_{out,nom}} = \frac{2}{\sqrt{1 + (4\pi \cdot f_{line} \cdot R_{LED} \cdot C_{out})^2}} \quad \text{(eq. 25)}$$

From Eq. 25, the following minimum value for $C_{out}$ can be deduced (Eq. 26):

$$C_{out,min} = \frac{4\pi \cdot f_{line,min} \cdot R_{LED,min}}{\sqrt{\left(\frac{2}{\left(\frac{\Delta I_{out,pk-pk}}{I_{out,nom}}\right)^2} - 1\right)}} \quad \text{(eq. 26)}$$

$C_{out}$ must then be large enough to avoid an excessive current ripple which could reduce the LED reliability. The flicker index is commonly specified below 0.15. This requirement corresponds to a 100% peak-to-peak ripple in a PF-corrected LED driver with a sinusoidal output current shape.

This criterion (100% peak to peak ripple), leads to:

$$\frac{(\Delta I_{out,pk-pk})_{out,nom}}{I_{out,nom}} = 1 \quad \text{(eq. 27)}$$

In our application the minimum LED dynamic resistance is estimated to be 6 \Omega and the minimum line frequency is 50 Hz. In this case, the minimum output capacitor value is:

$$C_{out,min} = \frac{\sqrt{\left(\frac{2}{100\%}\right)^2 - 1}}{6} \approx 460 \, \mu\text{F} \quad \text{(eq. 28)}$$

A 470 F/35 V is implemented.

**Bulk Capacitor Heating:**

It must also be checked that the ESR is low enough to prevent the rms current that flows through it, from overheating the bulk capacitor. This capacitor rms current can be estimated using the following expression.

$$I_{C_{rms}}^{(\text{max})} = \sqrt{\frac{32 \cdot \sqrt{2} \cdot \left(\frac{n_P}{n_S}\right)^2 \cdot \frac{(P_{in,\text{avg}})^{\text{max}}}{V_{in,\text{rms}}^2} \cdot \frac{V_{in,\text{rms}}}{V_{out,\text{rms}}}}{9\pi} \cdot \frac{V_{out,\text{rms}}}{N_{PS}} \left(1 + \frac{8}{3\pi} \cdot \frac{V_{out,\text{rms}}}{V_{in,\text{rms}}}ight) \cdot \frac{1}{N_{PS}} \cdot l_{out,nom}^2 \quad \text{(eq. 29)}$$

It remains wise to check the output capacitor heating in the lab.

**STEP 2: OUTPUT CURRENT SETTING**

As explained in the data sheet, the output current is regulated to equal the following $I_{out,nom}$ nominal output current:

$$I_{out,nom} = \frac{V_{REF}}{2N_{PS}R_{sense}} \quad \text{(eq. 30)}$$

Where:

- $N_{PS}$ is the secondary to primary transformer turns ratio $N_{PS} = n_S / n_P$
- $R_{sense}$ is the current sense resistor (see Figure 2)
- $V_{REF}$ is the output current internal reference.

Hence once the transformer is designed, $N_{PS}$ is known and the only current sense resistor dictates the output current level.
Hence:

\[
R_{\text{sense}} = \frac{250 \cdot 10^{-3}}{2 \cdot \frac{1}{500} \cdot 500 \cdot 10^{-3}} = 1.5 \ \Omega \quad (\text{eq. 33})
\]

And:

\[
P_{\text{loss}} = \frac{4}{3} \cdot 1.5 \left( \frac{12}{90} \right)^2 \left( 1 + \frac{8 \cdot \sqrt{2} \cdot 90}{3 \pi \cdot 176} \right) = 100 \ \text{mW} \quad (\text{eq. 34})
\]

Two 3 \ \Omega resistors are placed in parallel.

**Input Voltage Sensing and Feedforward:**

A portion of the input voltage must be applied to the \( V_S \) pin to provide the circuit with the sinusoidal reference necessary for shaping the input current (PFC). The obtained current reference is further modulated so that when averaged over a half-line period, it is equal to the output current reference \( V_{\text{REF}} \). This averaging process is made by an internal Operational Trans-conductance Amplifier (OTA) and the capacitor connected between the COMP pin and ground. The recommended minimum COMP capacitance is 1 \ \mu F.

**COMP Pin Capacitor**

A 1 \ \mu F capacitor is to be placed between COMP pin and ground.

**Input Voltage Sensing**

A resistors divider (\( R_{S1} \) and \( R_{S2} \) of Figure 2) provides pin 2 with the \( V_S \) signal. The scale-down factor is computed in accordance with the brown-out protection. If \( (V_{\text{in.rms}})_{\text{BOH}} \) is the targeted minimum line rms voltage necessary for entering operation, \( R_{S1} \) and \( R_{S2} \) must comply with:

\[
\frac{R_{S2}}{R_{S1} + R_{S2}} \cdot \sqrt{2} \cdot \left( \frac{V_{\text{in.rms}}}_{\text{BOH}} \cdot V_{\text{BO(on)}} \right) = V_{\text{BO(on)}} \quad (\text{eq. 35})
\]

Where \( V_{\text{BO(on)}} \) is the internal threshold (1 V typically) the \( V_S \) pin voltage must exceed to allow circuit operation. In other words,

\[
R_{S1} = R_{S2} \left( \sqrt{2} \cdot \left( \frac{V_{\text{in.rms}}}_{\text{BOH}} \cdot V_{\text{BO(on)}} \right) - 1 \right) \quad (\text{eq. 36})
\]

\( R_{S2} \) values in the range of 50 k\ \Omega generally provide a good tradeoff between losses and noise immunity. In our application, we select 47 k\ \Omega. Our system being supposed to enter operation when the line voltage exceeds 81 V rms:

\[
R_{S1} = 47 \cdot 10^{3} \cdot \left( \sqrt{2} \cdot \frac{81}{1} - 1 \right) = 5.4 \ \text{M}\ \Omega \quad (\text{eq. 37})
\]

It is generally recommended not to have a single resistor placed between a high-voltage rail and a low potential node. Instead, two or more resistors are to be placed in series. In our case, we use two 2,700 k\ \Omega resistors for \( R_{S1} \).

**Feedforward**

The NCL30088 computes the current setpoint \( (V_{\text{control}}) \) for power factor correction and proper regulation of the LED current. Now, the MOSFET cannot turn off at the very moment when the current-sense voltage exceeds \( V_{\text{control}} \). There actually exists a propagation delay \( t_{\text{prop}} \) (Figure 5) for which the primary current keeps rising. As a result, the primary current does not exactly peak to the expected \( (V_{\text{control}} / R_{\text{sense}}) \) value but to a higher level. The output current is hence also affected. Optimal regulation performance requires the peak current increase caused by \( t_{\text{prop}} \) to be compensated.
The NCL30088 compensates for the propagation delay by sourcing a current proportional to the \( V_S \) pin voltage out of the CS pin during the on-time. Placing a resistor \( R_{LFF} \) between the CS pin and the sense resistor, the following offset is hence obtained:

\[
V_{CS(\text{offset})} = K_{LFF} \cdot v_S(t) \cdot R_{LFF} \tag{eq. 38}
\]

Where the \( V_S \) pin voltage \( v_S(t) \) equates:

\[
v_S(t) = \frac{R_{S2}}{R_{S1} + R_{S2}} \cdot v_{in}(t) \tag{eq. 39}
\]

Since the CS pin offset must compensate for

\[
R_{LFF} = \left(1 + \frac{R_{S1}}{R_{S2}}\right) \cdot \frac{t_{prop} R_{\text{Sense}}}{L_p K_{LFF}} \tag{eq. 40}
\]

Where:

- \( K_{LFF} \) is the \( V_S \) pin voltage to CS pin current conversion ratio. Its typical value is 20 \( \mu \)S.
- \( R_{S1} \) and \( R_{S2} \) are the input voltage sensing resistors (see Figure 2).

Parameter \( t_{prop} \) includes the controller internal delay of the controller (about 50 ns) and the MOSFET turning off time. Thus, it varies with respect to the chosen MOSFET and the way it is driven (value of the gate resistors for instance). As a consequence, it is difficult to predict its exact value prior to evaluating the LED driver design.

### Selecting the CS Pin Capacitor

The shape of the current-sense voltage influences the output current regulation. If the CS pin filter \( (R_{LFF}, C_{CS}) \) is too big, the output current setpoint will vary \( (I_{out} \) higher than expected value). Thus, once \( R_{LFF} \) has been chosen, it is important to keep the value of \( C_{CS} \) as small as possible to have an optimal output current regulation. \( C_{CS} \) should be in the range of 10–100 pF.

Table 2.

NCL30088 proprietary regulation technique ensures a very precise LED current control. Please note that sources of deviation are however to be considered. They are detailed in [3]. Let’s recall the main points:

- The NCL30088 regulates the total current provided by the converter, that are, the LED current plus the \( V_{CC} \) current. Hence, the actual output current is:

\[
I_{\text{out,nom}} = \frac{N_P \cdot V_{\text{REF}}}{2 \cdot N_S} - \frac{N_{\text{Aux}}}{N_S} \cdot I_{CC} \tag{eq. 42}
\]

In general, the \( \left( \frac{N_{\text{Aux}}}{N_S} \cdot I_{CC} \right) \) term is small compared to the target LED current and can be ignored. If not, \( R_{\text{Sense}} \) should be reduced to compensate for the circuit consumption.

- The output current value depends on the sense resistor \( (R_{\text{Sense}}) \). Select a precise resistor and avoid long tracks that lead to an additional series resistance. If \( R_{\text{Sense}} \) is 1 \( \Omega \) and that the circuit additionally senses the voltage across a 20 m\( \Omega \) track, the total sensing resistor will be 1.02 \( \Omega \) instead of 1 \( \Omega \). Ultimately, the output current will 2% below target.

- Avoid inductive sense resistor. If not, the output current will be less than the target because of the offset the series inductor causes on the CS pin voltage:

\[
\left( \frac{I_{\text{Sense}}}{L_p} \cdot v_S(t) \right) \tag{eq. 41}
\]

However, for a first approximation, we can calculate \( R_{LFF} \), using \( t_{prop} = 200 \text{ ns} \).

Then, the offset resistor value can be fine-tuned on the bench so that the output current characteristic is nearly flat over the line voltage range.

Using Eq. 40, we can calculate the first value of \( R_{LFF} \) for our design:

\[
R_{LFF} = \left(1 + \frac{R_{S1}}{R_{S2}}\right) \cdot \frac{t_{prop} R_{\text{Sense}}}{L_p K_{LFF}} = \left(1 + \frac{5400}{47}\right) \cdot \frac{200 \times 1.5}{1900 \times 20} \approx 915 \Omega
\]

After experiments in the lab, \( R_{LFF} \) value was decreased to 820 \( \Omega \).

Important Note: As indicated in the NCL30088 data sheet, \( R_{LFF} \) must be selected higher than 250 \( \Omega \). If not, the circuit may improperly detect that the CS pin is grounded.

- The output current value depends on the sense resistor \( (R_{\text{Sense}}) \). Select a precise resistor and avoid long tracks that lead to an additional series resistance. If \( R_{\text{Sense}} \) is 1 \( \Omega \) and that the circuit additionally senses the voltage across a 20 m\( \Omega \) track, the total sensing resistor will be 1.02 \( \Omega \) instead of 1 \( \Omega \). Ultimately, the output current will 2% below target.

- Avoid inductive sense resistor. If not, the output current will be less than the target because of the offset the series inductor causes on the CS pin voltage:

\[
\left( \frac{I_{\text{Sense}}}{L_p} \cdot v_S(t) \right) \tag{eq. 41}
\]

However, for a first approximation, we can calculate \( R_{LFF} \), using \( t_{prop} = 200 \text{ ns} \).

Then, the offset resistor value can be fine-tuned on the bench so that the output current characteristic is nearly flat over the line voltage range.

Using Eq. 40, we can calculate the first value of \( R_{LFF} \) for our design:

\[
R_{LFF} = \left(1 + \frac{R_{S1}}{R_{S2}}\right) \cdot \frac{t_{prop} R_{\text{Sense}}}{L_p K_{LFF}} = \left(1 + \frac{5400}{47}\right) \cdot \frac{200 \times 1.5}{1900 \times 20} \approx 915 \Omega
\]

After experiments in the lab, \( R_{LFF} \) value was decreased to 820 \( \Omega \).

Important Note: As indicated in the NCL30088 data sheet, \( R_{LFF} \) must be selected higher than 250 \( \Omega \). If not, the circuit may improperly detect that the CS pin is grounded.
STEP 3: SD PIN MANAGEMENT

The Thermal Foldback and Shutdown block of the NCL30088 is inherited from the NCL30082 and its functioning and design is detailed in application note AND9131/D ([2]). Only key points will be highlighted here.

Selecting the SD Over-voltage Zener Diode

A Zener diode can be placed between the $V_{CC}$ and the SD pins. The circuit detects an OVP fault if the SD pin voltage exceeds 2.5 V. Note that the NCL30088 ensures that a 700 µA minimum current flows through the Zener diode in this case (see [1]) so that it can be operated far from its knee region. The SD OVP threshold on $V_{CC}$ is:

$$V_{CC,SD,OVP} = V_Z + V_{OVP} \quad (eq. \ 43)$$

Where $V_{OVP}$ is the 2.5-V SD OVP threshold.

An SD OVP fault is detected if $V_{CC}$ exceeds $(V_{CC,SD,OVP}$).

For instance, if you applied a Zener diode exhibiting an 18-V Zener breakdown voltage (when biased by a 700 µA current), the SD_OVP protection will trip when $V_{CC}$ exceeds $(18.0 + 2.5)$ volts, that is, 20.5 V. In this case, the NCL30088B/D stops operating for the auto-recovery 4 s delay. At the end of this time, the circuit attempts to resume operation. If the fault is still present, the circuit again detects an SD OVP fault and stops for 4 s. Finally, the NCL30088B or NCL30088D enters a safe, very low duty-ratio burst mode. An SD OVP fault leads the NCL30088A and NCL30088C to latch off until the LED driver is unplugged and $V_{CC}$ drops below $V_{CC}(\text{reset})$. At that moment, the fault is cleared and the circuit can resume operation.

Such a programmable protection feature is useful if the fixed $V_{CC}$ OVP protection which trips when $V_{CC}$ exceeds $V_{CC}(\text{OVP})$ (26.8 V typically) does not clamp the output voltage at a low enough level. This is not the case in our application. No Zener diode is hence implemented.

Selecting the Thermistor

The resistance of a Negative Coefficient Temperature thermistor (NTC) reduces when its temperature rises. An NTC is to be placed between the SD pin and ground to detect an over-temperature condition. In response to a high temperature, the circuit gradually reduces the LED current down 50% of its nominal value. If despite the current reduction, the temperature still increases, the circuit will eventually stop operation. In general a 50% reduction in current is more than a 50% drop dissipated power as the LED forward voltage will decrease as the current is folded back.

More specifically, as shown by Figure 6, $R_{th}$ designating the NTC resistance:

- The circuit starts to gradually reduce the output current when $R_{th}$ drops below $R_{TF(start)}$ and continues diminishing it until $R_{th}$ goes below $R_{TF(stop)}$.
- At that moment, it maintains the output current at 50% of its nominal level as long as $R_{th}$ is between $R_{TF(stop)}$ and $R_{OTP(off)}$. If on the contrary, a temperature decay leads $R_{th}$ to rise above $R_{TF(stop)}$, the current increases according the precedent characteristics. If $R_{th}$ exceeds $R_{TF(start)}$, full current capability is recovered.
- The LED driver totally stops operating if $R_{th}$ drops below $R_{OTP(off)}$ and stays off until the temperature having reduced, $R_{th}$ exceeds $R_{OTP(on)}$. At that moment, the circuit resumes (NCL30088B and NCL30088D only – A and C versions latch off) and delivers 50% of the nominal current.
- If $R_{th}$ further rises, the current regulation grows as well until $R_{th}$ reaches $R_{TF(start)}$. At that moment, the LED driver provides the full current.

![Figure 6. Thermal Foldback Characteristics and Over-temperature Protection](image-url)
As an example, if thermistor NB12P00104JBB from AVX is implemented:
- The circuit starts to reduce the output current at about 82°C ambient temperature.
- The circuit stops operation at about 104°C ambient temperature.
- The circuit recovers operating at about 90°C ambient temperature.

Selecting the SD Pin Capacitor
A small capacitor can be placed between the SD pin and ground to prevent the pin from picking up possible surrounding noise. Please note that the value of this capacitor must not exceed 4.7 nF so that it can charge to its nominal level before the OTP blanking time has elapsed.

NOTE: At start-up, the controller blanks the SD function until a delay of 250 µs minimum (OTP blanking time), has elapsed, to provide CSD with enough time to properly charge above the 0.5 V over-temperature threshold. If not, the low SD pin voltage will be considered as caused by the low-resistance of an NTC in excessive temperature conditions.

### STEP 4: AUXILIARY WINDING AND VCC MANAGEMENT

#### VCC Capacitor Refueling
In nominal operation, the auxiliary winding provides the VCC voltage as shown by Figure 2. The auxiliary winding number of turns (naux) is computed in the transformer section of the “Step 1” paragraph. Note that during the on-time, diode DAUX of Figure 2 rectifies the auxiliary voltage to provide VCC. Hence, neglecting the turn on spike, DAUX must be able to sustain:

\[ V_{DAUX} = V_{CC} + \left( \frac{naux}{np} \cdot \sqrt{2} \cdot (V_{in, rms})_{HL} \right) \]  

(eq. 44)

The VCC highest value is the maximum voltage the VCC(OVP) threshold can take (28.5 V). Therefore:

\[ V_{DAUX} = (V_{CC(OVP)})_{max} + \left( \frac{naux}{np} \cdot \sqrt{2} \cdot (V_{in, rms})_{HL} \right) \]  

(eq. 45)

In our case:

\[ V_{DAUX} = (V_{CC(OVP)})_{max} + \left( \frac{naux}{np} \cdot \sqrt{2} \cdot (V_{in, rms})_{HL} \right) = \]

\[ \approx 28.5 + \left( \frac{1}{6} \cdot \sqrt{2} \cdot 265 \right) \approx 91 \text{ V} \]  

(eq. 46)

Due to the turn on spike, some significant headroom is necessary. Selecting a diode exhibiting at least twice the computed VRRM value seems a good practice.

A 250 V/0.2 A BAV21 diode is implemented in our application.

#### VCC Capacitor Value and Startup Circuitry
When off (that is until VCC has reached the 18-V start-up level), the NCL30088 consumes a very low current (13 µA typically, 30 µA maximum). Thus, high-impedance, low dissipation, resistors can be used to charge the VCC capacitor at start-up.

Note however, that faults like a VCC over-voltage condition lead the LED driver to stop operation and refrain from attempting to recover until a 4 s delay is elapsed. A low duty-ratio burst mode of operation is hence obtained as long as the fault is present. VCC cycles up and down in such a case. For this time, the (off-mode) consumption is slightly higher (75 µA max.). It is hence recommended to have the startup current (Istartup in Figure 7) above 75 µA. If not, VCC may collapse and the circuit reset before the 4 s delay has elapsed.

As detailed in application note AND9131/D [2], the startup resistor Rstartup can either be connected to the bulk rail or to half-wave (Figure 7). Connecting the startup resistor to the half-wave allows decreasing the power dissipated in the startup resistor.
Calculating the $V_{CC}$ Capacitor

The $V_{CC}$ capacitor value ($C_{Vcc}$) must be large enough to feed the controller until the auxiliary winding voltage $V_{aux}$ is sufficiently large to supply the controller. The time duration where the controller is supplied by the only $C_{Vcc}$ capacitor is noted $t_{reg}$ (Figure 8).

The circuit enters operation when the $V_{CC}$ capacitor is charged to the $V_{CC}$ startup level. For the $t_{reg}$ duration, the $V_{CC}$ capacitor must be able to maintain the $V_{CC}$ voltage above the UVLO level ($V_{CC(0ff)}$) while providing the current consumed by the circuit ($I_{CC2}$ specified in the data sheet) and the current necessary to drive the MOSFET.

We can estimate $t_{reg}$ by considering that for this period of time, all the LED driver output current is absorbed by the output capacitor (no current flows through the LED string). $t_{reg}$ lasts until the output voltage reaches the level at which $V_{CC}$ starts to be charged. In general, we try to minimize the $C_{Vcc}$ capacitor by allowing a nearly maximal $V_{CC}$ capacitor discharge, that is, down to a value close to the UVLO level. At that moment, the output voltage will nearly be $\left(V_{out} = (V_{CC(0ff)})_{max} \frac{n_{aux}}{n_{aux}}\right)$ and $t_{reg}$ can then be computed as follows:

$$t_{reg} \approx \frac{C_{out}}{I_{out}} \left((V_{CC(0ff)})_{max} \frac{n_{aux}}{n_{aux}}\right)$$

(eq. 47)

Now, using the minimum value of the UVLO hysteresis (minimum value of $V_{CC(0ff)} - V_{CC(0ff)}$), the minimum $V_{CC}$ capacitor value comes:

$$C_{Vcc} \geq \frac{(I_{CC2} + Q_{g})_{reg}}{(V_{CC(HYS)})_{min}} \approx \frac{n_{aux}}{n_{aux}} \cdot \frac{C_{out}}{I_{out}} \cdot \frac{(V_{CC(0ff)})_{max}}{(V_{CC(HYS)})_{min}}$$

(eq. 48)

Where:
- $I_{CC2}$ is the NCL30088 consumption at 65 kHz when the DRV pin is unloaded (4 mA max)
- $Q_{g}$ is the MOSFET total gate charge
- $(V_{CC(HYS)})_{min}$ is the UVLO hysteresis minimum value (8 V)
75 μA so that as explained at the beginning of this section, the circuit does not reset in fault mode. Hence:

\[ I_{\text{startup}} = \frac{(V_{CC(on)})_{\text{max}} C_{Vcc}}{t_{\text{startup}}} + (I_{\text{CC(start)}})_{\text{max}} \]  
\[ I_{\text{startup}} = \begin{cases} 75 \mu A & \text{otherwise} \end{cases} \]

Where:
- \((V_{CC(on)})_{\text{max}}\) is the VCC startup threshold maximum value
- \((I_{\text{CC(start)}})_{\text{max}}\) is the maximum value of the NCL30088 startup consumption (30 μA)
- \(t_{\text{startup}}\) is the targeted startup time

In our case, assuming a 19-nC gate charge MOSFET, a 65-kHz operation and a 0.5-s target for the startup time, it comes: (Eq. 50 and Eq. 51)

\[ t_{\text{reg}} = \frac{C_{out} (I_{\text{CC(start)}} + Q_{\text{dss}} \text{t}_{\text{reg}})}{(V_{CC(HYS)})_{\text{min}}} = \frac{4m + 19n 65k}{8} = 6 \mu F \]

We will select a 10 μF/35 V capacitor. Hence:

\[ I_{\text{startup}} = \frac{(V_{CC(on)})_{\text{max}} C_{Vcc}}{t_{\text{startup}}} + (I_{\text{CC(start)}})_{\text{max}} = \frac{20 \cdot 10 \mu A}{0.5} + 30 \mu A = 430 \mu A \geq 75 \mu A \]  
\[ \text{(eq. 52)} \]

**Startup Resistor Calculation**

**Bulk Connection**

For start-up time, the bulk rail sees the line peak voltage (the input voltage becomes a rectified sinusoid when the LED driver starts to operate), the following formula gives the \( R_{\text{startup}} \) value:

\[ R_{\text{startup}} = \frac{\sqrt{2} \cdot (V_{\text{in,rms}})_{\text{LL}}}{I_{\text{startup}}} \]  
\[ \text{(eq. 53)} \]

Where:
- \( I_{\text{startup}} \) is the startup current
- \((V_{\text{in,rms}})_{\text{LL}}\) is the lowest line rms voltage

The maximum power dissipated by the startup resistor connected to the bulk rail is:

\[ P_{\text{startup}} = \frac{\left( \frac{\sqrt{2} \cdot (V_{\text{in,rms}})_{\text{HL}}}{\pi} - V_{\text{CC}} \right)^2}{R_{\text{startup}}} \]
\[ \leq \frac{2 \cdot (V_{\text{in,rms}})_{\text{HL}}^2}{R_{\text{startup}}} \]
\[ \text{(eq. 54)} \]

Where \((V_{\text{in,rms}})_{\text{HL}}\) is the highest line rms voltage.

**Half-wave Connection**

If the resistor is connected to the half-wave:

\[ R_{\text{startup1/2}} = \frac{\sqrt{2} \cdot (V_{\text{in,rms}})_{\text{LL}}}{I_{\text{Vcc}} + \frac{1}{I_{\text{CC(start)}}}} \]
\[ \text{(eq. 55)} \]

The maximum power dissipated by the startup resistor connected to the half-wave is thus:

\[ P_{\text{startup1/2}} = \frac{\left( \frac{(V_{\text{in,rms}})_{\text{HL}}}{\pi} \right)^2}{R_{\text{startup1/2}}} \leq \frac{94k}{265} \cdot \frac{265}{94} = 151 \text{ mW} \]
\[ \text{(eq. 58)} \]

Three 33-kΩ, 1/4 W resistors are placed in series.
ZCD Network

$R_{ZCD1}$ of Figure 2 limits:

- The current injected into the ZCD pin during the demagnetization time. As indicated in the data sheet, this current must remain below 5 mA.
- The current extracted from the ZCD pin during the on-time. This current must not exceed 2 mA.

During the on-time, the ZCD pin current is maximal at the highest line voltage:

$$I_{ZCD, on} = \frac{n_{aux} \sqrt{2} \cdot (V_{in, rms})_{HL}}{R_{ZCD1}} \leq 2 \text{mA} \quad (eq. \ 59)$$

During the demagnetization time, the auxiliary winding voltage is maximal when $V_{CC}$ is at its maximum value, that is, the OVP level. Hence:

$$I_{ZCD, dmg} = \frac{V_{CC(OVP)_{max}} + V_f}{R_{ZCD1} + R_{ZCD2}} \leq 5 \text{mA} \quad (eq. \ 60)$$

Where $V_{CC(OVP)_{max}}$ is the $V_{CC}$ maximum value for $V_{CC}$ OVP protection tripping (28.5 V).

For optimal output current regulation, it is recommended to keep the ZCD pin voltage below 5 V. This is the goal of $R_{ZCD2}$ of Figure 2.

$$R_{ZCD2} \cdot (V_{CC, max} + V_f) = 5 \text{V} \quad (eq. \ 61)$$

Where $V_{CC, max}$ is the maximal $V_{CC}$ voltage in normal operation (20 V in our application).

Finally, this resistor together with the $C_{ZCD}$ capacitor delays the zero-voltage crossing event and helps to tune the turn-on instant when the drain voltage is in the valley.

Finally: (see Table 4)

| Table 4. |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| $C_{VCC}$       | $R_{startup 1/2}$ | $R_{startup}$  | $D_{AUX}$      | $R_{ZCD1}$ / $R_{ZCD2}$ | $C_{ZCD}$     |
| 10 $\mu$F / 35 V | three 33 k$\Omega$, 1/4 W | N/A            | BAV21          | 33 k$\Omega$ / 10 k$\Omega$ | 22 pF      |

Finally:

- (see Table 4)

**Figure 9. Application Schematic**
Output Current Regulation

Figure 10 shows the output current as a percentage of its nominal value. We can see that its characteristic is very flat with respect to the temperature.

Thermal Foldback starts at about 80°C. As a result, the output current linearly decays to reach 50% of its nominal value at nearly 92°C. The circuit stops operating (SD pin Over Temperature Protection) at approximately 105°C and resumes operation when the temperature drops down to about 90°C. These temperature thresholds depend on the thermistor connected to the SD pin. Below characteristics were obtained with a NB12P00104JBB thermistor manufactured by AVX.

Power Factor

Figure 11 shows the power factor measured at two different line magnitudes (115 V rms and 230 V rms). The power factor is extremely stable over the considered temperature range from −40°C to 80°C. Above 80°C, the performance is affected by the thermal foldback which reduces the output current.
Fault Situations
The NCL30088 incorporates a large suite of protections. Next figures illustrate the circuit capability to address shorted/open situations of the LED string or an output diode failure. Tests have been made with the B version (NCL30088B). Application note AND9204/D discusses in details the NCL30088 behavior under safety tests [4].

Open LED String Situation
The LED string being disconnected, the \( V_{CC} \) voltage rises and the \( V_{CC(OVP)} \) protection trips when \( V_{CC} \) exceeds 26.8 V (typically). At that moment, the circuit stops operating for the 4-s auto-recovery delay. The LED driver recovers normal operation when the LEDs are again connected.

LED String Short Situation
As illustrated by Figure 14, if the output is shorted, the AUX_SCP protection makes the LED driver enters a safe, low duty-ratio burst mode. Normal operation is recovered when the short is removed. The same behavior would be obtained with the D version. Note that the NCL30088A and NCL30088C latch off when an output short is detected. No recovery is hence possible with these versions until the LED driver is unplugged and \( V_{CC} \) drops below \( V_{CC(reset)} \). At that moment, the fault is cleared and the circuit can resume operation.
Figure 14. The System Enters a Safe Low Duty-ratio Burst Mode when the Output is Shorted (the LED Driver Output is Shorted for about 10 s for this Test)

Output Diode Short
The LED driver stops operation as soon as 4 faulty DRV pulses are detected (see Figure 16). In this situation, the NCL30088B and NCL30088D attempt to resume operation when the 4-s auto-recovery delay is elapsed. The NCL30088A and NCL30088C remain latched off until the system is reset.

Figure 15. NCL30088B Operation when the Output Diode is Shorted
Figure 16. The Winding or Output Diode Short Circuit Protection (WODSCP) Trips as soon as 4 Consecutive Faulty DRV Pulses are Detected
