Circuit Description

The NCP785A is a high–performance linear regulator, offering a very wide operating input voltage range of up to 450 V DC, with an output current of up to 10 mA. Ideal for high input voltage applications such as industrial and home metering, home appliances. The NCP785A family offers ±5% initial accuracy, extremely high–power supply rejection ratio and ultra–low quiescent current. The NCP785A is optimized for high–voltage line and load transients, making this part ideal for harsh environment applications.

The NCP785A is offered in fixed output voltage options 3.3 V, 5.0 V, 12 V and 15 V. SOT–89 package offers good thermal performance and help to minimize the solution size.

This circuit is designed to operate as a non–isolated off–line power supply with minimum external parts producing a fixed voltage 3.3 V output from a standard wide range input voltage from 85 Vac up to 265 Vac. It provides a maximum output current of 10 mA. The output ripple is significantly reduced by a linear regulator topology which has very high PSRR (70dB typ.) over the frequency range of 50 Hz to 120 Hz. This low ripple output voltage is suitable for supplying various smart metering systems sensitive to power line pollution. The NCP785A is optimized for high–voltage line and load transients, making it ideal for harsh environment applications.

Performance Information

The following Figures show typical measured performance of the NCP785A in this evaluation board.

Figure 4. Maximum Output Current & Power Dissipation vs. Input Voltage

Figure 5. Output Voltage vs. Temperature
The chart in Figure 4. shows the maximum allowable output current at different input voltages for 3% output voltage falling. The power dissipation of 2.35 W limits the maximum output current of the reference design board. Figure 5 shows the thermal characteristics of the board where the output voltage decreases with increasing junction temperature. The oscillogram in Figure 6. shows typical output voltage behavior a few seconds after starting from room temperature with overloading. The overheating invokes the repetitive activation thermal shutdown protection and the output voltage is quickly switched on and off and the behavior looks like oscillation. Figure 7. shows the temperature map of the reference PCB. You can see how the top side copper helps spread the thermal load across the board and reduce the junction temperature of the part.

Application Recommendations

Maximum allowed output current is strongly limited by power dissipation and proper cooling conditions. The Figure 8. shows the SOT89-3 package maximum power dissipation and ThetaJA dependence on the cooper area for single side board, based on the basic thermal equation (eq.1).

\[
P_{D(MAX)} = \frac{T_{J(MAX)} - T_A}{\Theta_{JA}} \quad (eq. 1)
\]

Figure 8. Maximum Power Dissipation & ThetaJA vs. Copper Area

Figure 9. Maximum Power Dissipation vs. DC Input Voltage
In the real application it is very useful to check the maximum temperature on the case of the device by a thermal imaging camera. Figure 9. Shows calculated maximum output current dependence on the input voltage for three different Copper areas.

The power supply based on NCP785A linear regulator is ideal for microcontroller applications with very low consumption in stand-by or sleep mode for more than 90% of working time and for short time the device is able to deliver high current up to maximum capability limited by power dissipation for data transfer or another operations. The typical application example shown here is a wireless Bluetooth thermometer. Figure 10. shows the typical timing and consumption characteristics of this application. The average current is 249.7 uA and the total power consumption from 235 Vac main is below 83 mW. The consumption of SMPS in this application is usually 2 – 5 times higher and 2 – 5 times more expensive. The 66 uA consumption at sleep time is given by sum of 10 uA quiescent current and 56 uA microcontroller consumption in sleep mode. In case the average current exceed 500 uA the efficiency of the power supply based on NCP785A device rapidly fall. The current peak 3.7 mA during radio communication could be increased up to 10 mA but there is necessary to keep the duration of this current as short as possible.

Figure 10. Timing and consumption characteristic
Input Capacitor Selection

The input capacitor $C_{in}$ must maintain the regulator minimum input voltage 25 V at full load for AC voltage as low as 85 Vac.

For half wave rectification the recommended value is $C_{in}=2.2\,\mu F$, the rectifier waveforms are shown in Fig. 11. Lower capacitor values would limit the maximum output current; only 6.5 mA can be achieved with $C_{in}=1\,\mu F$. If the application can be floating, it is possible to use full wave rectifier which assures the minimum input voltage at NCP785A with input capacitor 1uF up to 10 mA load. The waveforms for this case are shown in the Figure 12.

**Figure 12.** Output Voltage at $V_{in}=85\,\text{Vac}$, full-wave rectifier, $C_{in}=1\,\mu F$, $I_{load}=10\,\text{mA}$
Conclusion

The NCP785A linear regulator allows you to create a simple and cost effective non-isolated power supply. This approach is a more efficient solution for low output power applications compared to a complex switching converter or capacitive dropper. Maximum output current is limited by power dissipation given by PCB layout and Input Voltage.
