FAN5602 — Universal (Step-Up/Step-Down) Charge Pump Regulated DC/DC Converter

Features
- Low-Noise, Constant-Frequency Operation at Heavy Load
- High-Efficiency, Pulse-Skip (PFM) Operation at Light Load
- Switch Configurations (1:3, 1:2, 2:3, 1:1, 3:2, 2:1, 3:1)
- 92% Peak Efficiency
- Input Voltage Range: 2.7V to 5.5V
- Output Current: 4.5V, 100mA at VIN = 3.6V
- ±3% Output Voltage Accuracy
- ICC < 1µA in Shutdown Mode
- 1MHz Operating Frequency
- Shutdown Isolates Output from Input
- Soft-Start Limits Inrush Current at Startup
- Short-Circuit and Over-Temperature Protection
- Minimum External Component Count
- No Inductors

Applications
- Cell Phones
- Handheld Computers
- Portable RF Communication Equipment
- Core Supply to Low-Power Processors
- Low-Voltage DC Bus
- DSP Supplies

Description
The FAN5602 is a universal switched capacitor DC/DC converter capable of step-up or step-down operation. Due to its unique adaptive fractional switching topology, the device achieves high efficiency over a wider input/output voltage range than any of its predecessors. The FAN5602 utilizes resistance-modulated loop control, which produces lower switching noise than other topologies. Depending upon actual load conditions, the device automatically switches between constant-frequency and pulse-skipping modes of operation to extend battery life.

The FAN5602 produces a fixed regulated output within the range of 2.7V to 5.5V from any type of voltage source. High efficiency is achieved under various input/output voltage conditions because an internal logic circuit automatically reconfigures the system to the best possible topology. Only two 1µF bucket capacitors and one 10µF output capacitor are needed. During power on, soft-start circuitry prevents excessive current drawn from the supply. The device is protected against short-circuit and over-temperature conditions.

The FAN5602 is available with 4.5V and 5.0V output voltages in a 3x3mm 8-lead MLP package.

Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Functional Description

FAN5602 is a high-efficiency, low-noise switched capacitor DC/DC converter capable of step-up and step-down operations. It has seven built-in switch configurations. Based on the ratio of the input voltage to the output voltage, the FAN5602 automatically reconfigures the switch to achieve the highest efficiency. The regulation of the output is achieved by a linear regulation loop, which modulates the on-resistance of the power transistors so that the amount of charge transferred from the input to the flying capacitor at each clock cycle is controlled and is equal to the charge needed by the load. The current spike is reduced to minimum. At light load, the FAN5602 automatically switches to Pulse Frequency Modulation (PFM) mode to save power. The regulation at PFM mode is achieved by skipping pulses.

Linear Regulation Loop

The FAN5602 operates at constant frequency at load higher than 10mA. The linear regulation loop consisting of power transistors, feedback (resistor divider), and error amplifier is used to realize the regulation of the output voltage and to reduce the current spike. The error amplifier takes feedback and reference as inputs and generates the error voltage signal. The error voltage signal is then used as the gate voltage of the power transistor and modulates the on-resistance of the power transistor and, therefore, the charge transferred from the input to the output is controlled and the regulation of the output is realized. Since the charge transfer is controlled, the FAN5602 has a small ESR spike.

Switch Array

Switch Configurations

The FAN5602 has seven built-in switch configurations, including 1:1, 3:2, 2:1 and 3:1 for step-down and 2:3, 1:2 and 1:3 for step-up.

When 1.5 x V_IN > V_OUT > V_IN, the 1:1 mode shown in Figure 21 is used. In this mode, the internal oscillator is turned off. The power transistors connecting the input and the output become pass transistors and their gate voltages are controlled by the linear regulation loop, the rest of power transistors are turned off. In this mode, the FAN5602 operates exactly like a low dropout (LDO) regulator and the ripple of the output is in the micro-volt range.

When 1.5 x V_IN > V_OUT > V_IN, the 2:3 mode (step-up) shown in Figure 22 is used. In the charging phase, two flying capacitors are placed in series and each is charged to a half of the input voltage. In pumping phase, the flying capacitors are placed in parallel. The input is connected to the bottom the capacitors so that the top of the capacitors is boosted to a voltage that equals V_IN/2 + V_IN, i.e., 3/2 x V_IN. By connecting the top of the capacitors to the output, one can ideally charge the output to 3/2 x V_IN. If 3/2 x V_IN is higher than the needed V_OUT, the linear regulation loop adjusts the on-resistance to drop some voltage. Boosting the voltage of the top of the capacitors to 3/2 x V_IN by connecting V_IN the bottom of the capacitors, boosts the power efficiency 3/2 times. In 2:3 mode, the ideal power efficiency is V_OUT/1.5 x V_IN. For example, if V_IN = 2V, V_OUT = 2 x V_IN = 4V, the ideal power efficiency is 100%.

When 2 x V_IN > V_OUT > 1.5 x V_IN, the 1:2 mode (step-up) shown in Figure 23 is used. Both in the charging phase and in pumping phase, two flying capacitors are placed in parallel. In charging phase, the capacitors are charged to the input voltage. In the pumping phase, the input voltage is placed to the bottom of the capacitors. The top of the capacitors is boosted to 2 x V_IN. By connecting the top of the capacitors to the output, one can ideally charge the output to 2 x V_IN. Boosting the voltage on the top of the capacitors to 2V_IN boosts the power efficiency 2 times. In 1:2 mode, the ideal power efficiency is V_OUT/2 x V_IN. For example, V_IN = 2V, V_OUT = 2 x V_IN = 4V, the ideal power efficiency is 100%.

When 3 x V_IN > V_OUT > 2 x V_IN, the 1:3 mode (step-up) shown in Figure 24 is used. In charging phase, two flying capacitors are placed in parallel and each is charged to V_IN. In the pumping phase, the two flying capacitors are placed in series and the input is connected to the bottom of the series connected capacitors. The top of the series connected capacitors is boosted to 3 x V_IN. The ideal power efficiency is boosted 3 times and is equal to V_OUT/3V_IN. For example, V_IN = 1V, V_OUT = 3 x V_IN = 3V, the ideal power efficiency is 100%. By connecting the output to the top of the series connected capacitors, one can charge the output to 3 x V_IN.

The internal logic in the FAN5602 monitors the input and the output compares them, and automatically selects the switch configuration to achieve the highest efficiency.

The step-down modes 3:2, 2:1, and 3:1 can be understood by reversing the function of V_IN and V_OUT in the above discussion.

The built-in modes improve power efficiency and extend the battery life. For example, if V_OUT = 5V, mode 1:2 needs a minimum V_IN = 2.5V. By built-in 1:3 mode, the minimum battery voltage is extended to 1.7V.

Light-Load Operation

The power transistors used in the charge pump are very large in size. The dynamic loss from the switching the power transistors is not small and increases its proportion of the total power consumption as the load gets light. To save power, the FAN5602 switches, when the load is less than 10mA, from constant frequency to pulse-skipping mode (PFM) for modes 2:3(3:2), 1:2(2:1) and 1:3(3:1), except mode 1:1. In PFM mode, the linear loop is disabled and the error amplifier is turned off. A PFM comparator is used to setup an upper threshold and a lower threshold for the output. When the output is lower than the lower threshold, the oscillator is turned on and the charge pump starts working and keeps delivering charges from the input to the output until the output is higher than the upper threshold. The oscillator shuts off power transistors and delivers the charge to the output from the output capacitor. PFM operation is not used for Mode 1:1, even if at light load. Mode 1:1 is designed as an LDO with the oscillator off. The power transistors at LDO mode are not switching and therefore do not have the dynamic loss.

Switching from linear operation to PFM mode (ILOAD<10mA) and from PFM to linear mode (ILOAD>10mA) is automatic, based on the load current, which is monitored all the time.

Short Circuit

When the output voltage is lower than 150mV, the FAN5602 enters short-circuit condition. In this condition, all power transistors are turned off. A small transistor shorting the input and the output turns on and charges the output. This transistor stays on as long as the VOUT <150mV. Since this transistor is very small, the current from the input to the output is limited. Once the short at the output is eliminated, this transistor is large enough to charge the output higher than 150mV and the FAN5602 enters soft-start period.

Soft Start

The FAN5602 uses a constant current, charging a low-pass filter to generate a ramp. The ramp is used as reference voltage during the startup. Since the ramp starts at zero and goes up slowly, the output follows the ramp and inrush current is restricted. When the ramp is higher than bandgap voltage, the bandgap voltage supersedes ramp as reference and the soft start is over. The soft start takes about 500µs.

Thermal Shutdown

The FAN5602 goes to thermal shutdown if the junction temperature is over 150°C with 15°C hysteresis.
Application Information

Using the FAN5602 to Drive LCD Backlighting

The FAN5602 4.5V option is ideal for driving the backlighting and flash LEDs for portable devices. One FAN5602 device can supply the roughly 150mA needed to power both the backlight and the flash LEDs. Even though drawing this much current from the FAN5602 drives the part out of the 3% output regulation, it is not a problem. The backlight and flash LEDs still produce optimal brightness at the reduced regulation. When building this circuit, use ceramic capacitors with low ESR. All capacitors should be placed as close as possible to the FAN5602 in the PCB layout.
