The FL7760 is a constant current step-down CCM controller for wide output power LED lighting applications. The FL7760 adapts hysteretic reference architecture that accurately regulates LED current by sensing voltage across an external high side sense resistor. This control scheme can stabilize LED current against input voltage and output load transient condition and implement optimal PWM and analog dimming control. Time delay control method widens analog dimming range down to less than 5%.

FL7760 has low 200 mV reference voltage to maximize system efficiency and high frequency driving capability so that system profile can be minimized in wide scale power ranges.

The FL7760 implements PWM and analog dimming together through a DIM pin and provides thermal shutdown (TSD), and under-voltage lockout (UVLO) protections.

Features
• Wide Input Range (8 VDC~70 VDC)
• Continuous Conduction Mode Operation
• Hysteretic LED Current Control
• Wide analog dimming range down to 5%
• Wide PWM dimming duty range to 0.2% at 2 kHz PWM freq.
• High switching frequency up to 1 MHz
• High source / sink current of 1.5 A / 2.5 A
• Cycle–by–Cycle Peak Current Limit
• Low Operating Current (300 uA)
• Low Stand–by Current (240 uA)

Typical Applications
• LED Lighting System

APPLICATION INFORMATION

General
The FL7760 is a step down hysteretic LED current controller that is easily configured in varies input voltage range from 8 V to 70 V. The converter employs a high side current sensing resistor to detect and regulate the LED current. Analog, PWM and hybrid dimming can be easily implemented with single DIM pin. In addition, the time delay control operation can realize analog dimming less than 5%.

Continuous Conduction Mode Regulation
The FL7760 employs hysteretic reference architecture that accurately regulates LED current by detecting an external high–side current–sense resistor voltage. The voltage across the current sensing resistor is kept measured and regulated in 200 mV±15% range. This control scheme performs stable LED current regulation at input voltage and load transient conditions.

VIN biasing at startup
Internal VIN biasing circuit quickly charges external VCC capacitor to begin IC operation. During the initial start–up, the VCC pin voltage gradually increases, and when the voltage reaches 4.5 V, the IC starts operating by VCC good signal.

Soft Start
The hysteretic reference voltage to regulate LED current is proportional to DIM voltage. Internal current source [6 uA] charges an external capacitor connected at DIM pin and soft start time can be programmable with capacitances. Soft start time can be calculated as below equation.

\[ T_{\text{Soft Start}} = \frac{C_{\text{DIM}} \times 3V}{6uA} \]  

Analog Dimming
When DIM voltage is higher than 3 V, hysteretic reference voltage is set to 200 mV±30 mV. This hysteretic reference condition limits LED current ripple spec of ±15% without storage capacitor in parallel with the LED string.

The control range of the DIM pin in analog dimming is from 3 V to 0.5 V. As DIM voltage decreases, hysteretic generated and the MOSFET is turned on, the LED current is still close to zero in the crossover distortion area where the input voltage is lower than the LED forward voltage.
references are reduced accordingly with the fixed +/-30 mV hysteresis. To perform wide analog dimming range to less than 5%, the FL7760 has Time Delay Control (built in version A) with hysteresis control. In this delay control method, gate is not turned on during the delay time determined by DIM voltage once \( V_{\text{VIN}} - V_{\text{SEN}} \) reaches to the low reference. Therefore, operating mode is entered into DCM (Discontinuous Current Mode) that makes non-linear dimming curve in low DIM voltage range.

Therefore, for analog dimming application with wide dimming requirement, version A is recommended and for PWM dimming application with linear dimming curve, version B is preferred.

![Figure 19. Analog Dimming Curve](image)

**PWM Dimming**

If the DIM pin voltage is less than 0.45 V for 1 us blanking time, FL7760 stops switching. When the DIM voltage is up again over 0.5 V for the blanking time, switching begins. Based on the blanking time, the minimum duty ratio for PWM dimming can be calculated as 0.2% for a 2 kHz dimming signal.

![Figure 20. PWM Dimming](image)

**Hybrid Dimming**

The FL7760 can implement hybrid dimming by adjusting amplitude and duty ratio of the single DIM signal provided at DIM pin. It provides wide dimming range with good dimming linearity.

![Figure 21. Hybrid Dimming](image)

**Standby Operation**

When the voltage of the DIM pin falls below 0.45 V for 34 ms, standby mode is entered and the power consumption of the control circuitry is minimized. Standby mode is terminated once DIM voltage is over 0.5 V.

![Figure 22. Standby Mode](image)

**Thermal Shut Down**

If internal junction temperature is higher than 150°C, TSD protection is triggered and released with 30°C hysteresis.

**Selection the Input Capacitor**

A low ESR input capacitor reduces the surge current and switching noise drawn from the front end power supply. Ceramic capacitors (100 ~ 120 nF) closely connected to VIN and GND pin can be effective in bypassing switching noise generated from front-end power stage and FL7760 buck converter stage.
Single layer PCB layout guidance

C\textsubscript{IN} bypass capacitor is closely connected to VIN and GND pins.

C\textsubscript{DIM} bypass capacitor is closely connected to DIM and GND pins.

Sensing resistor is connected close at VIN and SEN pins.

VCC capacitor is connected close at VCC pin.

SG and PG are combined and connected close at GND pin.
