LB8503V

DC Fan Motor Speed Control IC

Overview
The LB8503V is an improved functionality version of the LB8500 and LB8502 products that features the added functions listed below. The LB8503V supports both single-phase and three-phase applications.

Added Functions
- Supports Origin Shifting in the Speed Control Function
- Adds a Dedicated Pin for Setting the Soft Start Time:
  This allows a longer start time to be set without reducing the response time when changing speed.
- FG Output Pin Added

Functions and Features
- Achieves Linear Speed Control:
  Applications can set the slope of the change in motor speed with change in the input duty.
- Minimized Speed Fluctuations in the Presence of Line or Load Variations
- Allows a Minimum Speed to be Set
- Soft Start Function
- Settings Using External Capacitors and Resistors
  (to Support Easier Mass Production of End Products)
- Supports both PWM Duty and Analog Voltage Control Inputs

Figure 6.
Supplementary Operational Descriptions

The LB8503V accepts a duty pulse input and an FG signal from the driver IC, and generates the driver IC control voltage so that the FG period (motor speed) becomes proportional to the control voltage.

As shown in the figure below, the LB8503V generates a pulse signal from edges on the FG signal and then generates a pulse width waveform determined by the RC time constant in a one-shot multivibrator. The LB8503V then integrates that pulse waveform to create the output driver IC control voltage (a DC voltage).

It is also possible to change the slope of the VCTL/speed relationship as shown in the speed control diagram in the previous section by changing the pulse width with the RC time constant. Note, however, that since pulses determined by this RC time constant are used, variation in the RC components will appear as speed control errors.
**Pin Setting Procedures**  
(Provided for Reference Purposes)

[**RC Pin**]

The slope in the speed control diagram is determined by the RC pin time constant.

![Figure 9](image_url)

1. Determine the FG signal frequency \( f_{FG} \text{ (Hz)} \) at the motor’s highest speed.  
   (When 2 FG pulses are created on each motor revolution.)
   \[
   f_{FG} \text{ (Hz)} = \frac{2 \text{ rpm}}{60} \quad \text{(eq. 1)}
   \]

2. Determine the time constant for the RC pin.  
   (Let DUTY be the control duty at the highest motor speed. For example, 100% = 1.0, 60% = 0.6)
   \[
   R \times C = \frac{\text{DUTY}}{3 \times 0.85 \times f_{FG}} \quad \text{(eq. 2)}
   \]

3. Determine the resistor and capacitor values.  
   The range of capacitors that can be used is from 0.01 to 0.015 \( \mu \text{F} \) due to the charge capabilities of the RC pin circuit.  
   Therefore, an appropriate resistor value can be determined from either (eq. 3) or (eq. 4) below from the result obtained in step above.
   \[
   R = \frac{R \times C}{0.01 \mu \text{F}} \quad \text{(eq. 3)}
   \]
   \[
   R = \frac{R \times C}{0.015 \mu \text{F}} \quad \text{(eq. 4)}
   \]

Note that the temperature characteristics of the curve are determined by the temperature characteristics of the capacitor connected to the RC pin.  
A capacitor with excellent temperature characteristics must be used to minimize motor speed variation with temperature.
[CVO and CVI Pins]
These pins determine the origin of the slope. (To set the origin to 0% at 0 rpm, short CVO to CVI.)

1. X axis shift (Resistor dividing the CVO to ground potential).

To shift the characteristics from a 0% = 0 rpm origin to a situation where the speed at a duty of 30% is shifted to 0%:
First, determine the required CVI pin input voltage at 0%.
\[
CVI = 6 - (4 \times DUTY) = 6 - (4 \times 0.3) \quad \text{(eq. 5)}
\]
\[
CVI = 6 - 1.2 = 4.8 \text{ V}
\]
Next, when CVO is 6 V, determine the resistor values for the resistor divider between CVO and ground such that the midpoint becomes 4.8 V.

\[
\frac{\text{CVO} - \text{CVI}}{\text{CVI} - \text{ground}} = \frac{1.2 \text{ V}}{4.8 \text{ V}} = \text{a ratio of 1:4} \quad \text{(eq. 6)}
\]

From the above, the desired resistor values will be 20 k\(\Omega\) between CVO and CVI and 80 k\(\Omega\) between CVI and ground.
Note that the slope will change. (In this case, since the resistor ratio is 1:4, the result will be 4/5 of (or 0.8 times) the original slope.)
If required, the RC pin resistor value must be changed to correct the slope.
2. Y axis shift
(Resistor dividing the CVO to \( V_{CC} \) potential)

![Graph showing Y axis shift](image)

To shift the characteristics from a 0% = 0 rpm origin to a situation where the speed is 0 rpm at a duty of 30%:

First, determine the required CVO pin input voltage at 0%.

\[
CVO = 6 - (4 \times DUTY) = 6 - (4 \times 0.25) \\
= 6 - 1 = 5 \text{ V} 
\text{(eq. 7)}
\]

Determine the resistor values such that at \( CVO = 5 \text{ V} \), \( CVI \) becomes 6 V.

\[
\frac{CVO - CVI}{CVI - V_{CC}} = \frac{1}{6} = \text{a ratio of 1:6} 
\text{(eq. 8)}
\]

From the above, the desired resistor values will be 20 k\( \Omega \) between CVO and CVI and 80 k\( \Omega \) between CVI and ground.

(Due to the current capability of the CVO pin, the total resistor value must exceed 100 k\( \Omega \).)

Note that the slope will change. (In this case, since the resistor ratio is 1:6, the result will be 6/7 of (or 0.86 times) the original slope.) If required, the RC pin resistor value must be changed to correct the slope.
[LIM Pin]

The minimum speed is determined by the LIM pin voltage.

![Figure 14](image)

1. Determine the ratio of the required minimum speed and the maximum speed.

\[ R_a = \frac{\text{minimum speed}}{\text{maximum speed}} \]  
\[ \text{(eq. 9)} \]

In the example in the figure above:

\[ R_a = \frac{3000}{10000} = 0.3 \]  
\[ \text{(eq. 10)} \]

2. Determine the product of the duty that produces the maximum speed and the value from Equation 9.

\[ C_a = \text{maximum speed duty} \times R_a \]  
\[ \text{(eq. 11)} \]

For example:

\[ C_a = 0.9 \times 0.3 = 0.24 \]  
\[ \text{(eq. 12)} \]

3. Determine the required LIM pin voltage:

\[ \text{LIM} = 6 - (4 \times C_a) \]  
\[ \text{(eq. 13)} \]

For example:

\[ \text{LIM} = 6 - (4 \times 0.24) = 5 \text{ V} \]  
\[ \text{(eq. 14)} \]

4. Generate the LIM voltage by resistor dividing the 6 V regulator voltage.

For example, the resistor ratio to create a 5 V level will be 1:5.

Thus the resistor values will be 10 kΩ between 6 VREG and LIM and 51 kΩ between LIM and ground.

![Figure 15](image)
[C Pin]
Since a capacitor that can smooth the pin voltage is connected to the C pin, if the CTL pin input signal frequency is $f$ (Hz), then the capacitor must meet the following condition. (Here, $R$ is the IC internal resistance of 180 $\Omega$ (typical).)

$$\frac{1}{f} = t < RC \quad (eq. 15)$$

Note that the larger the capacitor, the slower its response to changes in the input signal will be.

![Figure 16.](image-url)
APPLICATION EXAMPLE 2

[Setting the Minimum Speed for an Origin of 0% = 0 rpm]

Figure 17.

When the speed control diagram origin is 0% = 0 rpm, the CVO pin is connected to the CVI pin. If the minimum speed is not set, connect the LIM pin to the 6 VREG pin.
When the speed control diagram origin is set so the motor turns at 0%, the CVO pin to ground potential difference is resistor divided and the midpoint is input to the CVI pin.

The speed at 0% can be changed with the resistor ratio.
APPLICATION EXAMPLE 4

[Origin Shift in the X Axis Direction (The Motor Turns at a Duty of 10% or Higher) Plus a Minimum Speed Setting]

Figure 21.

Figure 22.

When the origin in the speed control diagram is set so that the motor starts turning when the duty is above 0%, the potential difference between the CVO pin and VCC is resistor divided, and that divided level is input to the CVI pin.

The duty at which rotation starts can be changed by changing the resistor ratio.

Note that the total value of the resistors R4 and R5 must exceed 100 kΩ.
[DC Voltage Speed Control]

Figure 23.

When the motor speed is controlled by a DC voltage, than voltage must be in the range from 2 V to 6 VREG.

Note that the motor stops when the control voltage is at 6 VREG, and the motor speed increases as the voltage falls.
With this circuit, the motor speed remains constant even if there are fluctuations in the supply voltage or static voltage. It is also possible to input a fixed-duty signal to the CTL pin signal input as an input signal for which soft start is enabled at startup.
In this circuit, the dynamic range of the LB8503V EO pin (the range from the amplifier block output high to output low levels) must be wider than the dynamic range (from the high to low levels of the PWM signal) of VTH pin of driver IC with which this IC is combined.

However, since the LB11660FV PWM low-level voltage is lower than the LB8503V amplifier output low-level voltage, it must be resistor divided.
